PDV Workshop

Las Vegas, NV, USA

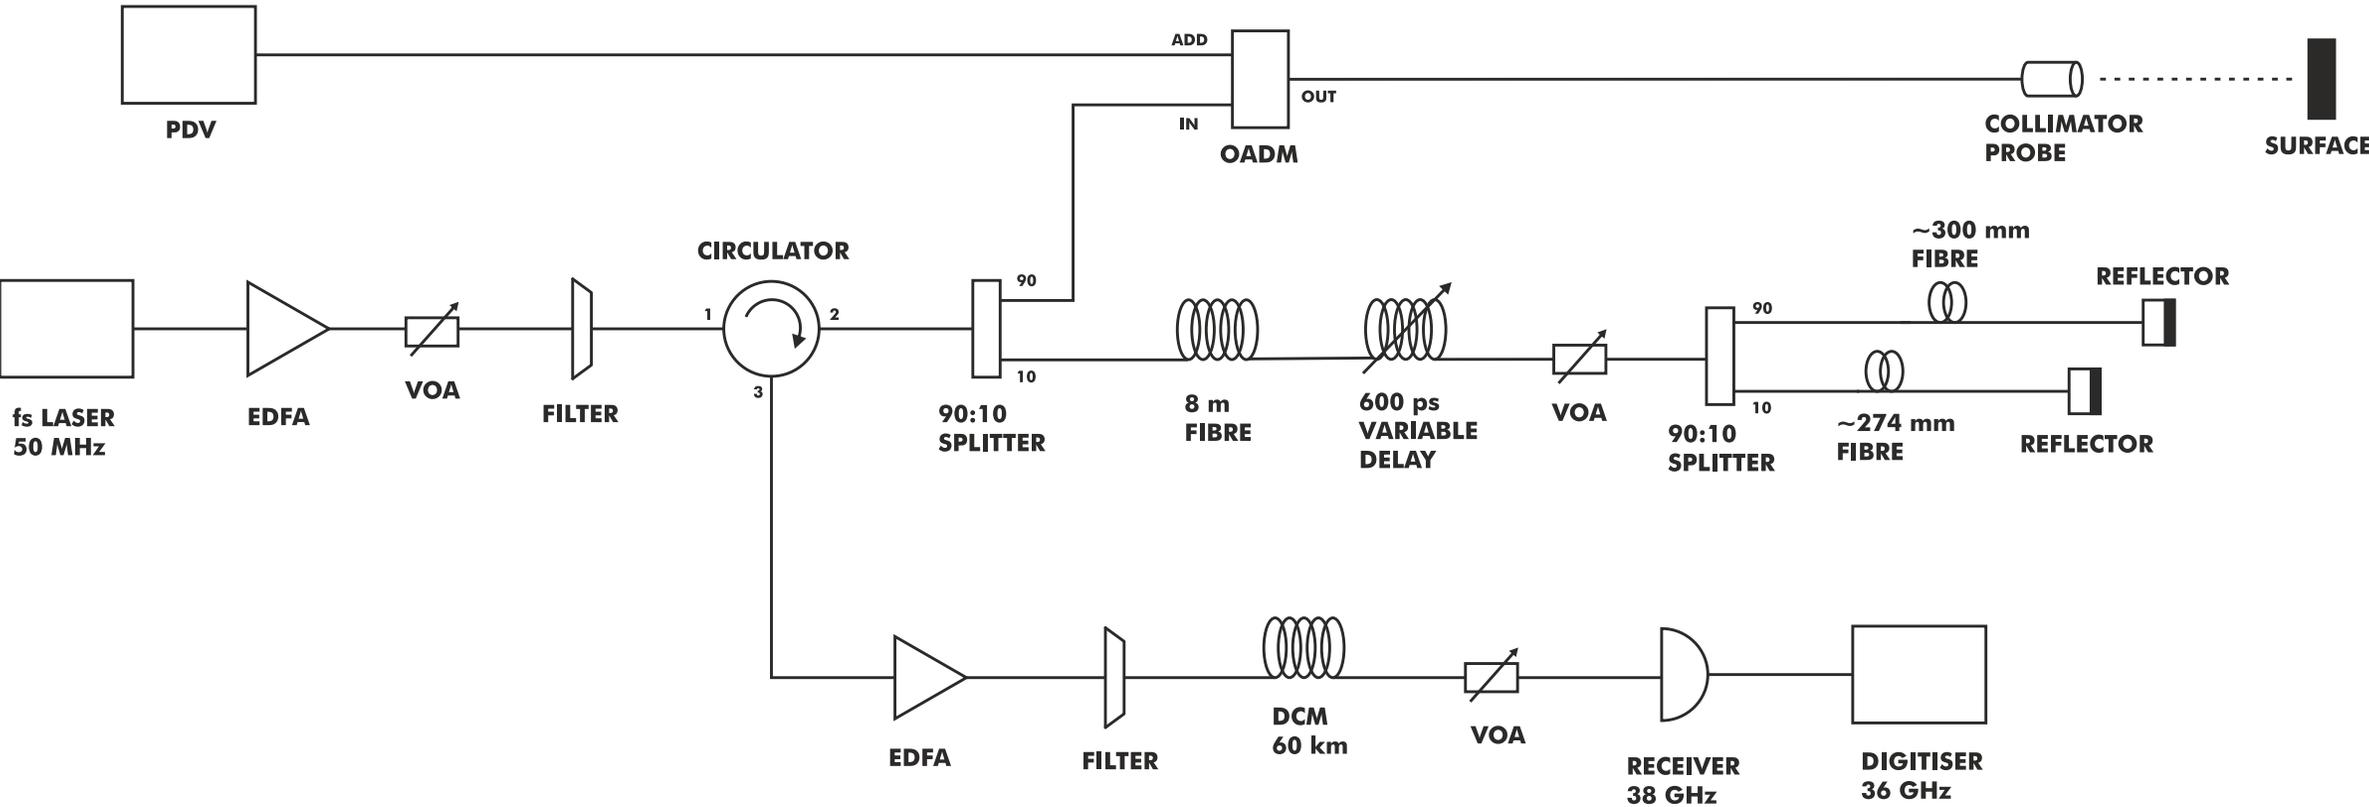

Broadband Laser Ranging (BLR)

- Broadband femtosecond pulsed time-of-flight diagnostic
- Surface pulse and reference pulse temporally combined with spectral dispersion to generate distance-dependent beat frequency
- Compliments existing Photonic Doppler Velocimetry (PDV) systems – combined on the same probe using an Optical Add/Drop Multiplexer
- A series of explosive firings were carried out to evaluate a Michelson interferometer BLR architecture
 - Previous work involved dynamic tests with a Mach-Zehnder system
- A frequency-upshifted PDV system was fielded simultaneously

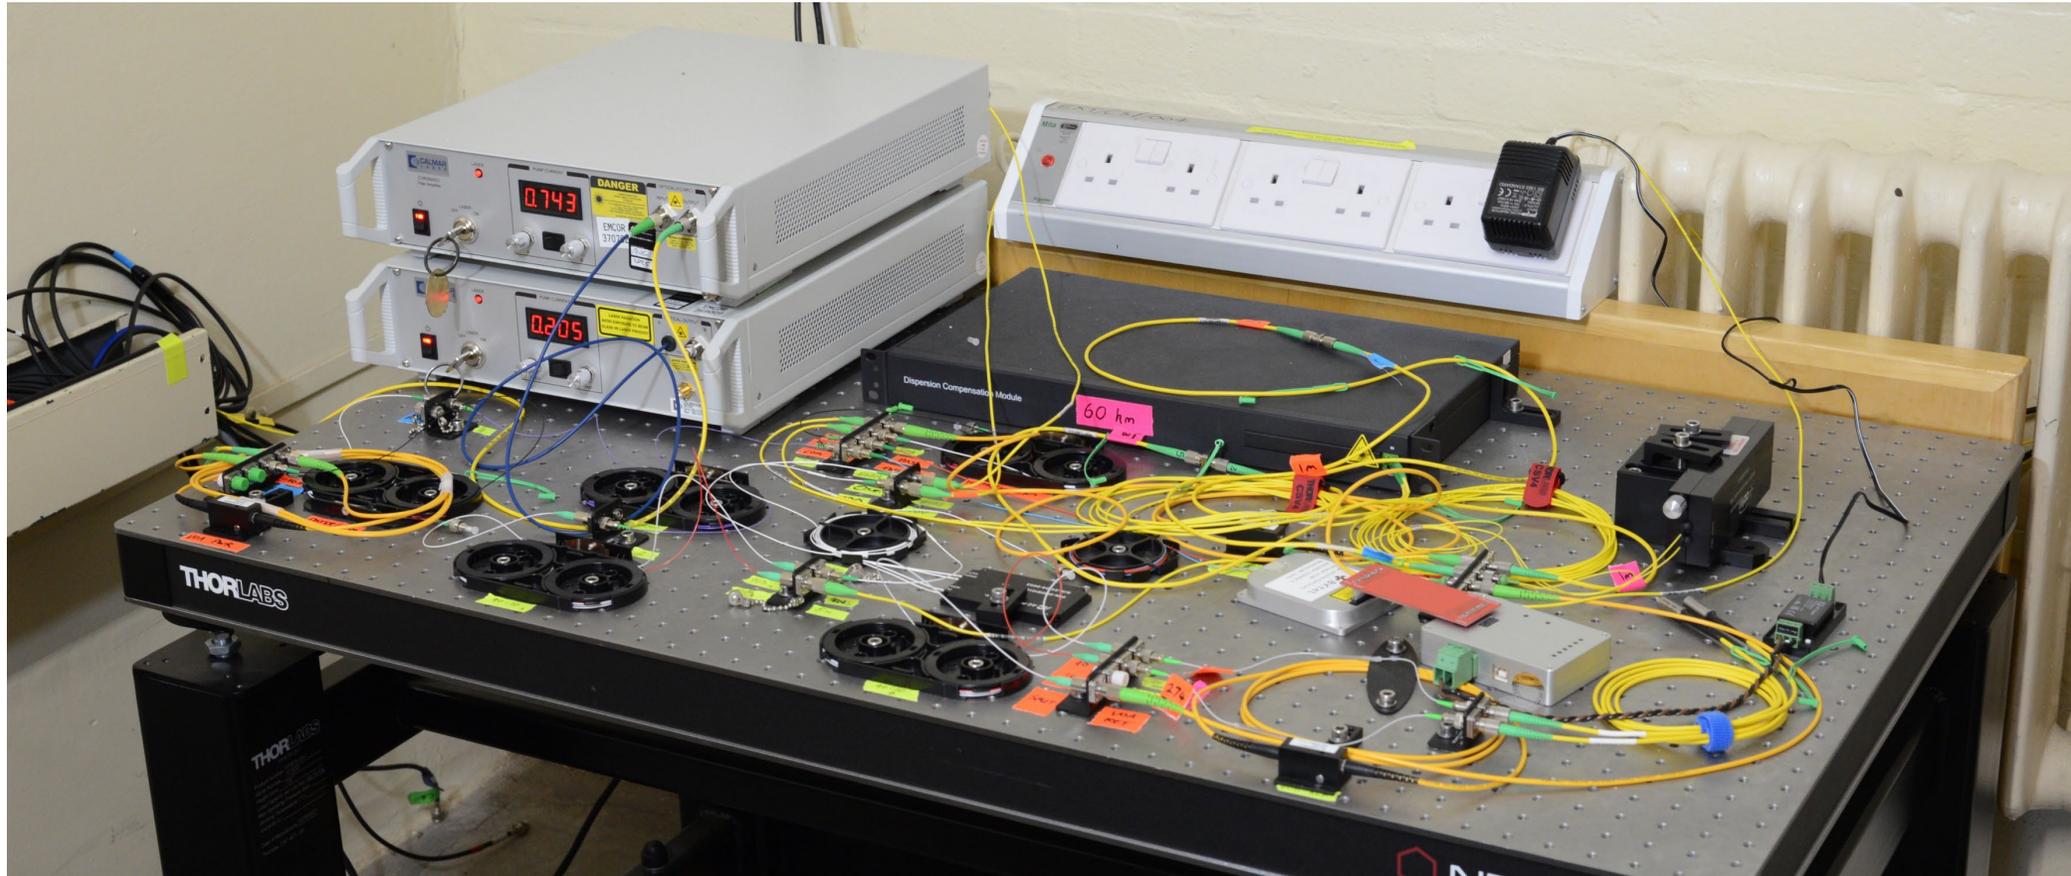

Previous BLR system: Mach–Zehnder interferometer

Current BLR system: Michelson interferometer

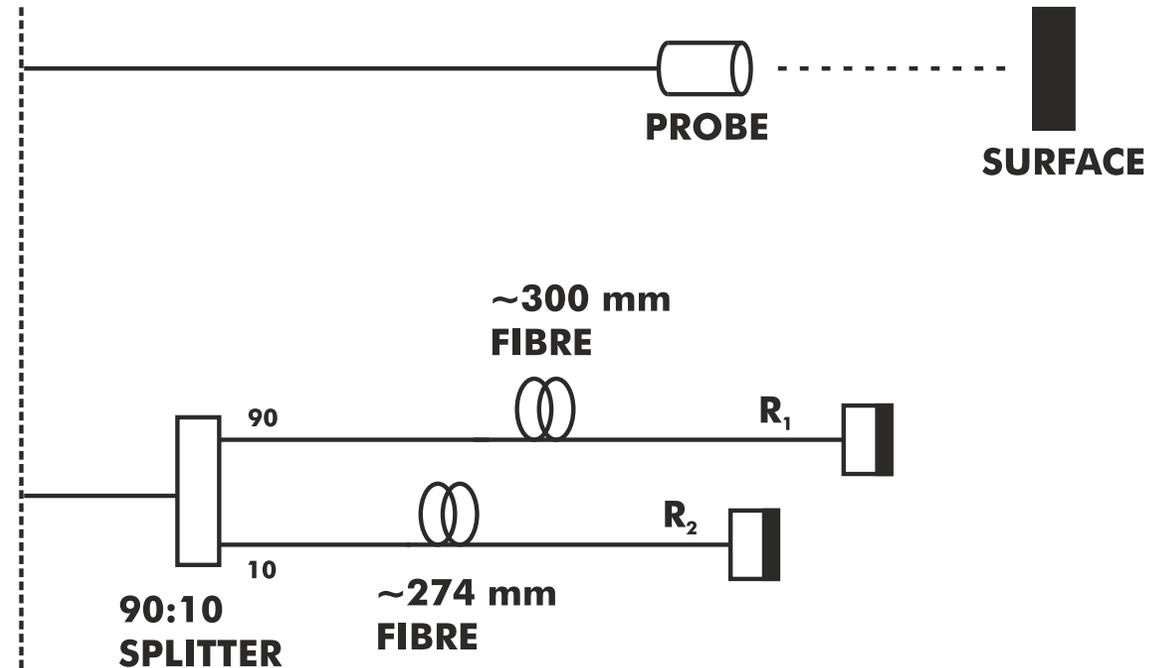

Current BLR system: Michelson interferometer

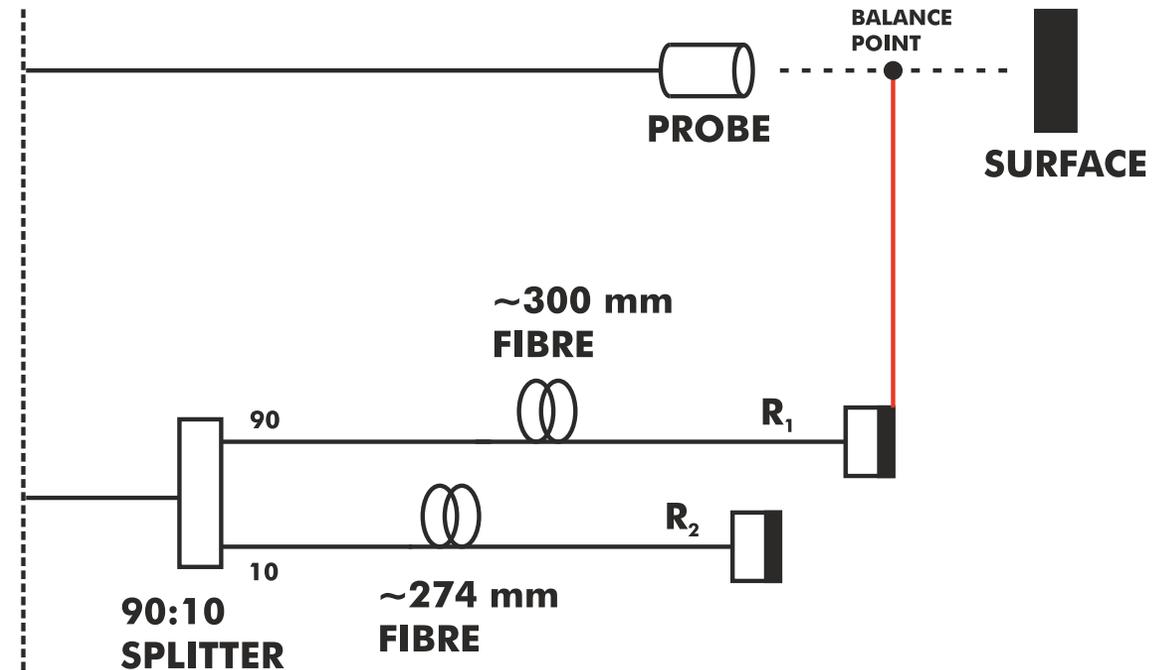

In-situ calibration

- Fixed path length difference between R_1 and R_2
- Path length difference 29.8 mm per Optical Backscatter Reflectometry (OBR) measurement
- 34.9 GHz beat frequency
- $(29.8 \text{ mm} * 1.4682) / 34.9 \text{ GHz} = 1.25 \text{ mm/GHz}$ system sensitivity
- R_2 is shorter than main path to delay beat frequency between surface and R_2 until after surface has reached the balance point

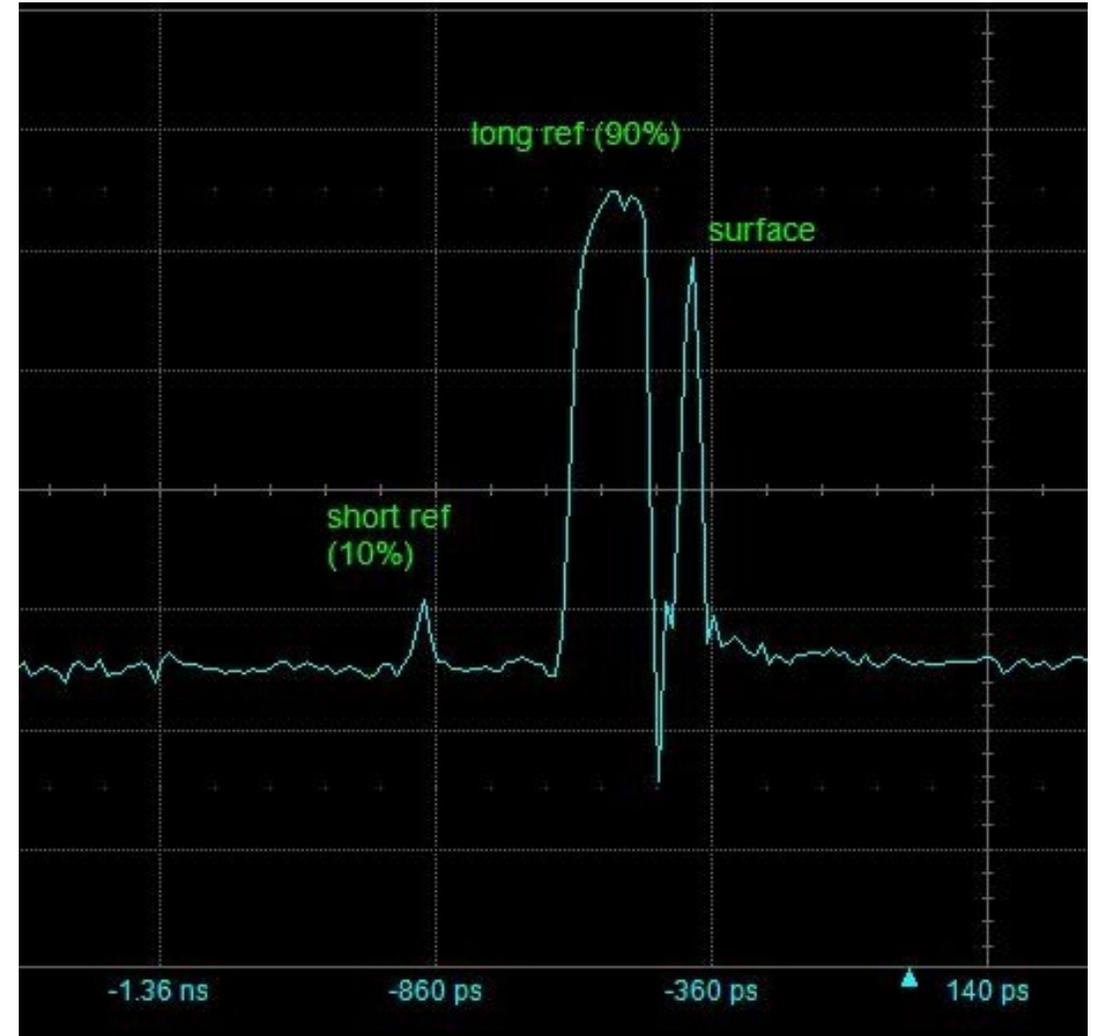

Reference length

- Set reference path length halfway between probe and surface for double-ended operation
- 600 ps adjustable delay provides 1.2 ns round-trip adjustment of reference leg
- Time domain check carried out first with DCM bypassed (i.e. no dispersion), then FFT for fine tuning of path length

Time domain check

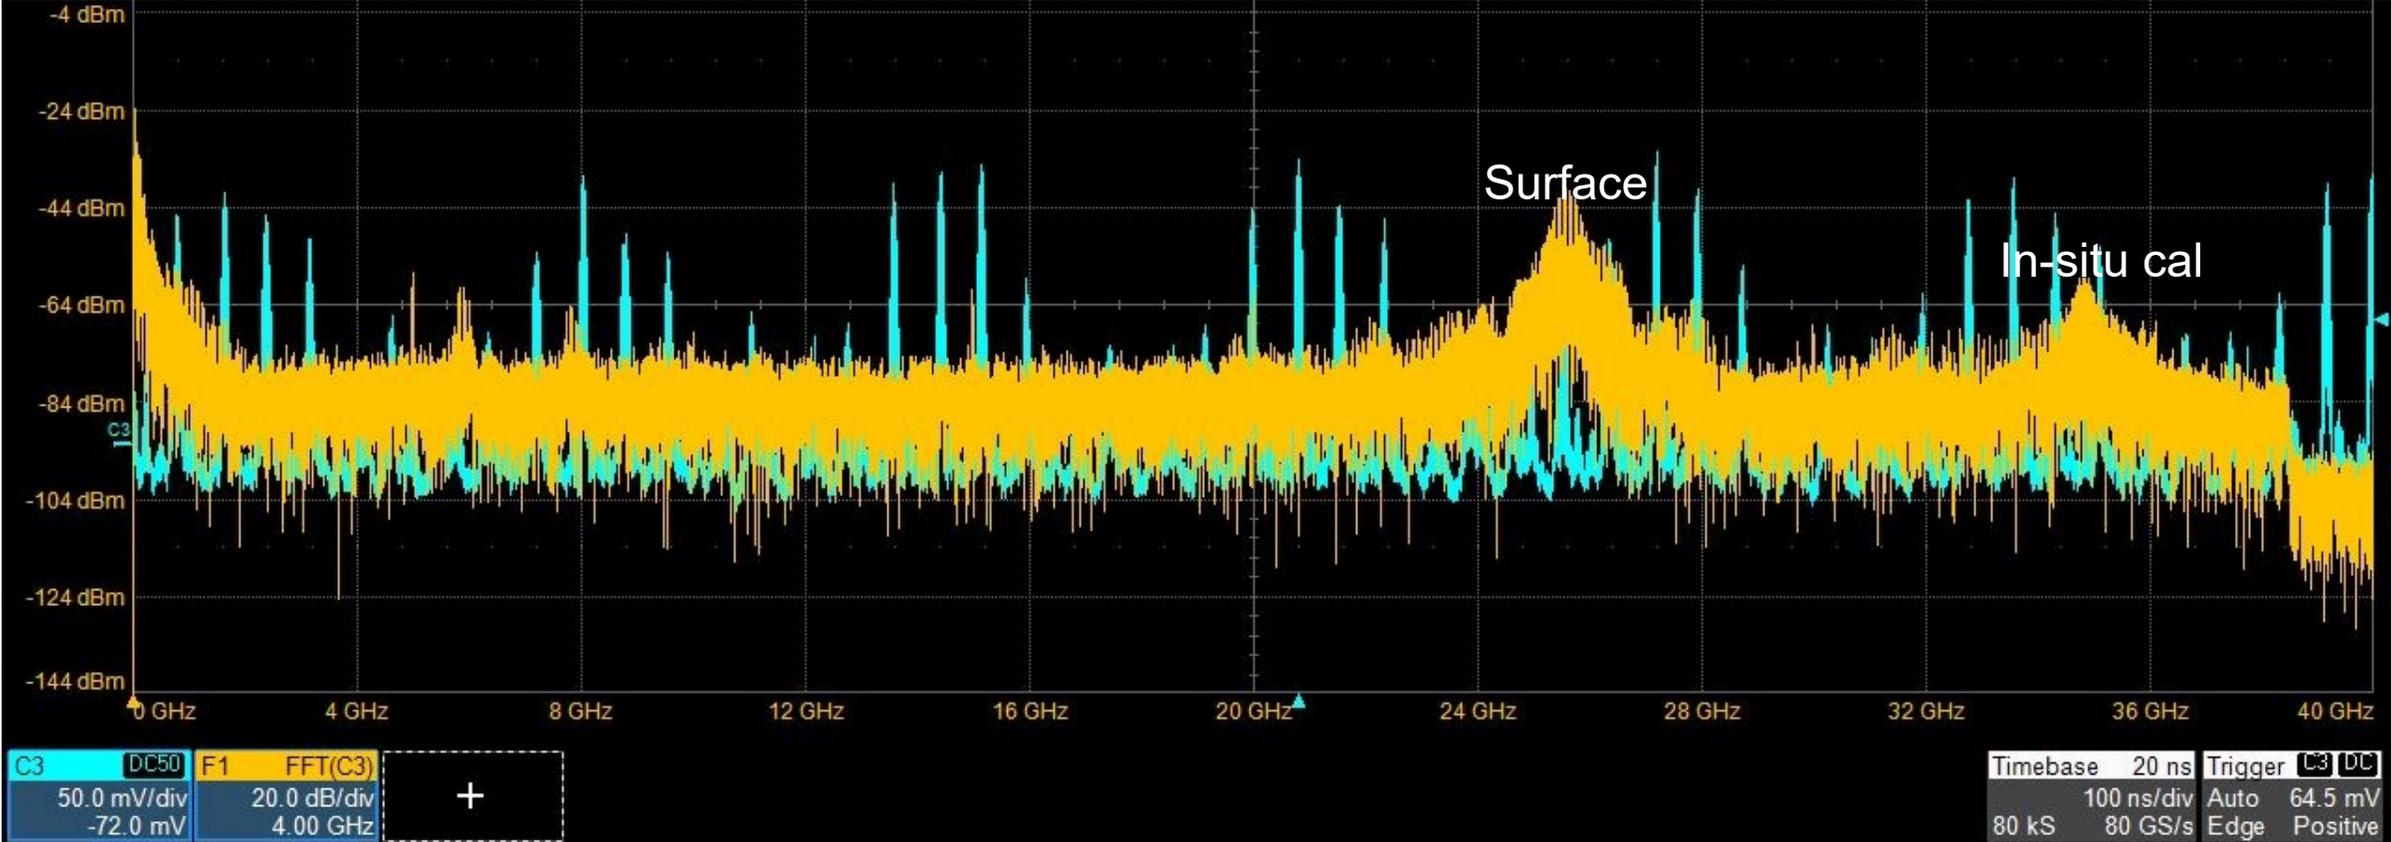

- R_1 pulse should come 100s of picoseconds before surface pulse in time domain with the DCM bypassed
- R_1 identified by adjusting variable optical attenuator on reference path
 - Reference pulse will change in amplitude while surface pulse remains constant
- Surface can be identified using retroreflective tape

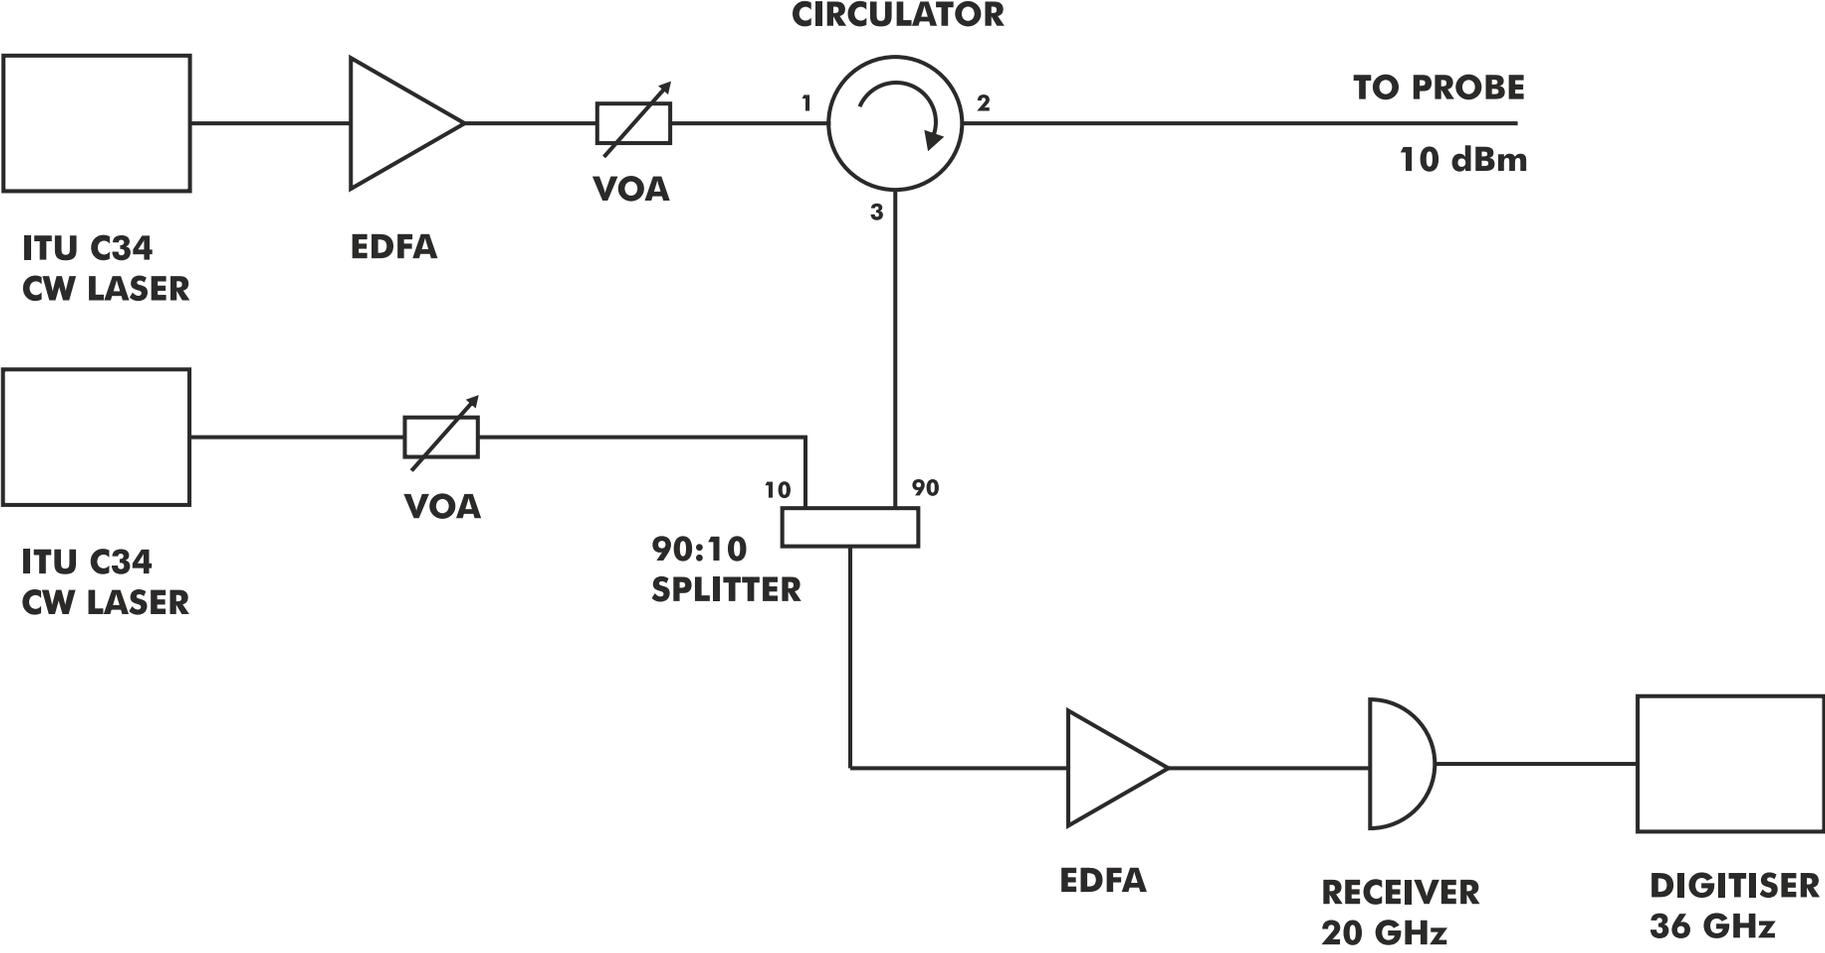

Frequency domain check

- Run FFT on digitiser
- In-situ cal. line should peak at 34.9 GHz
- Surface peak will be visible, assuming time domain check was successful
- Move surface towards probe slowly – surface peak will go to 0 GHz and back (double ended)

Frequency domain check

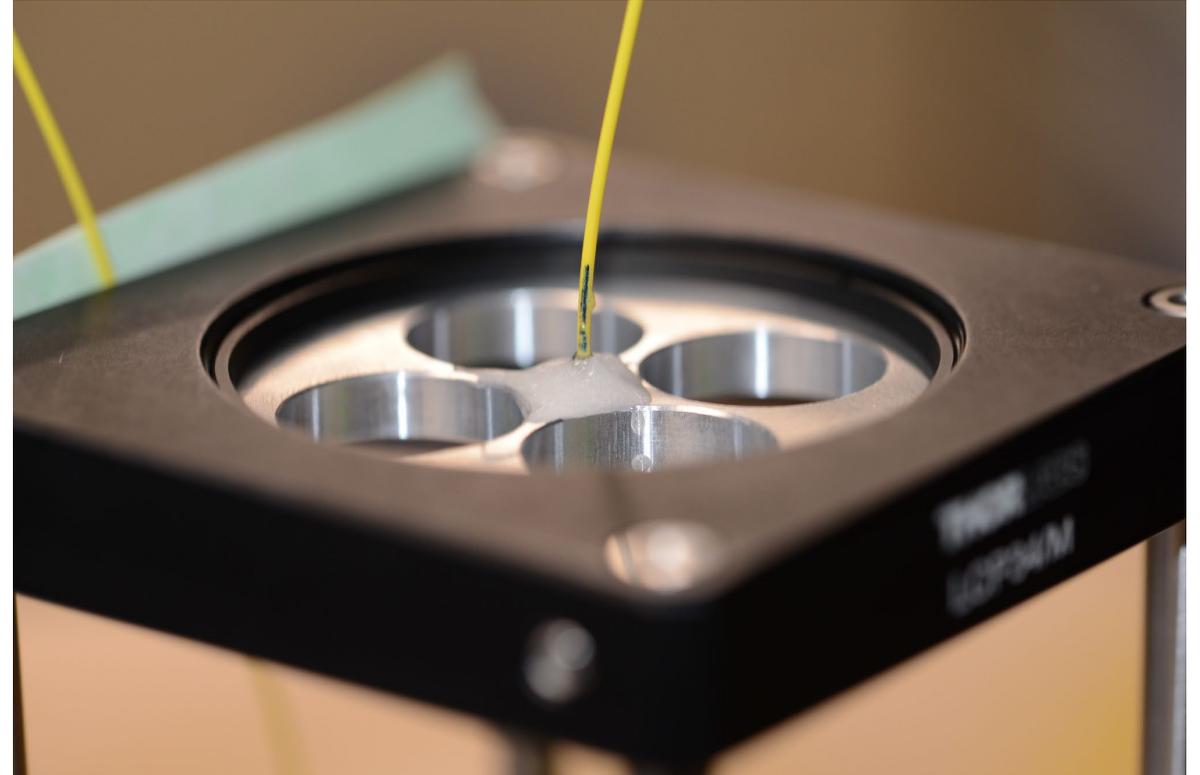

Simplified PDV system diagram

Experiments

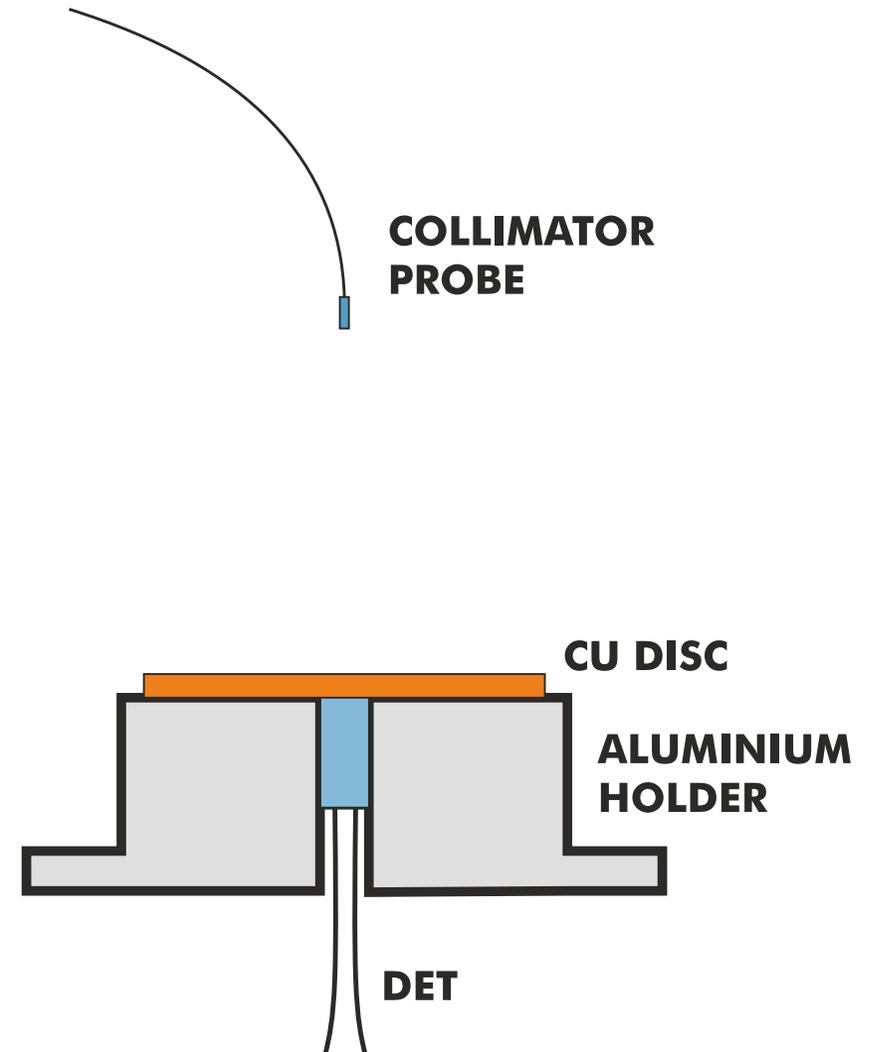

- 60 mm optomechanical cage system used to hold parts in alignment
- Collimator ~220 μm beam diameter
 - Attached with two-part epoxy or two-part epoxy putty
 - Aligned using visible laser to a hole in another cage plate to ensure measurement along cage axis

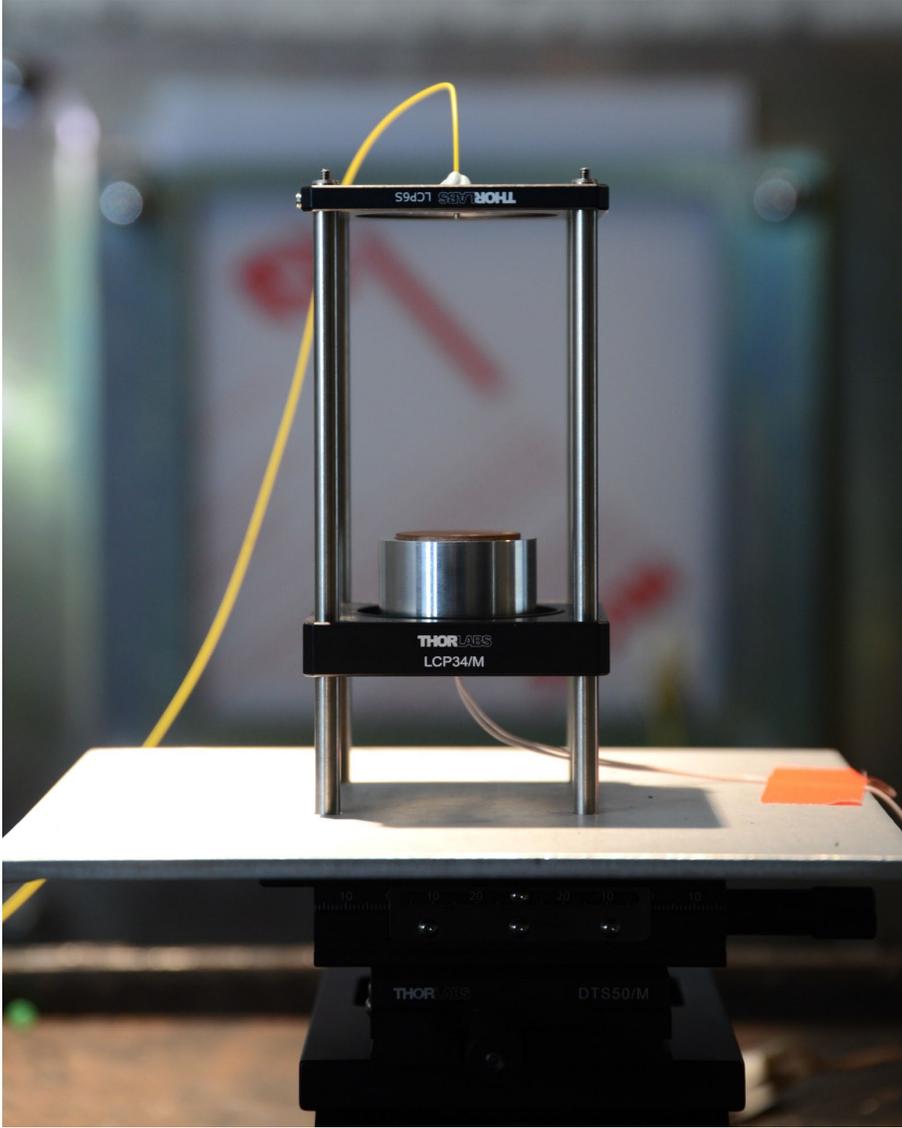

Experiment 1: Cu Disc

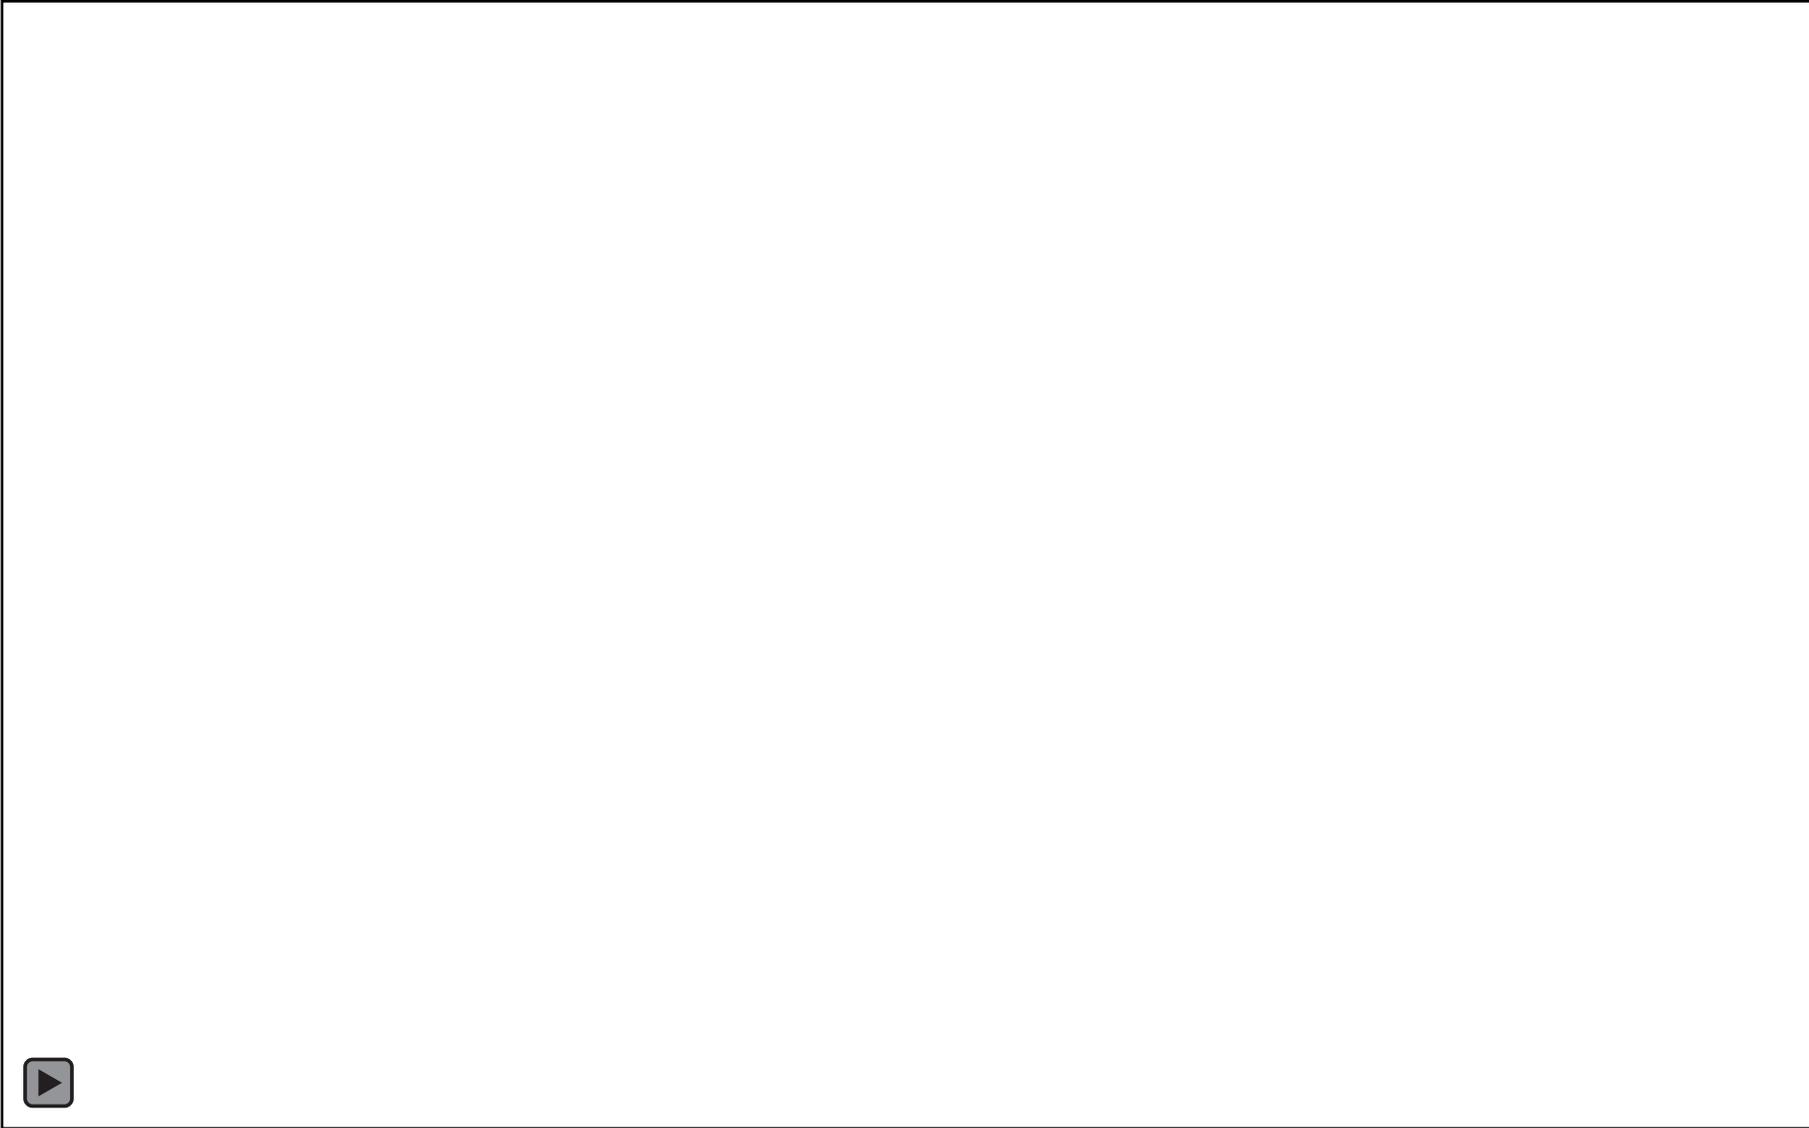

- Detonator drives 2 mm thick, 30 mm diameter copper disc
- Disc surface bead blasted for consistent return signal
- Probe aligned to centre of disc
- Disc expected to fragment

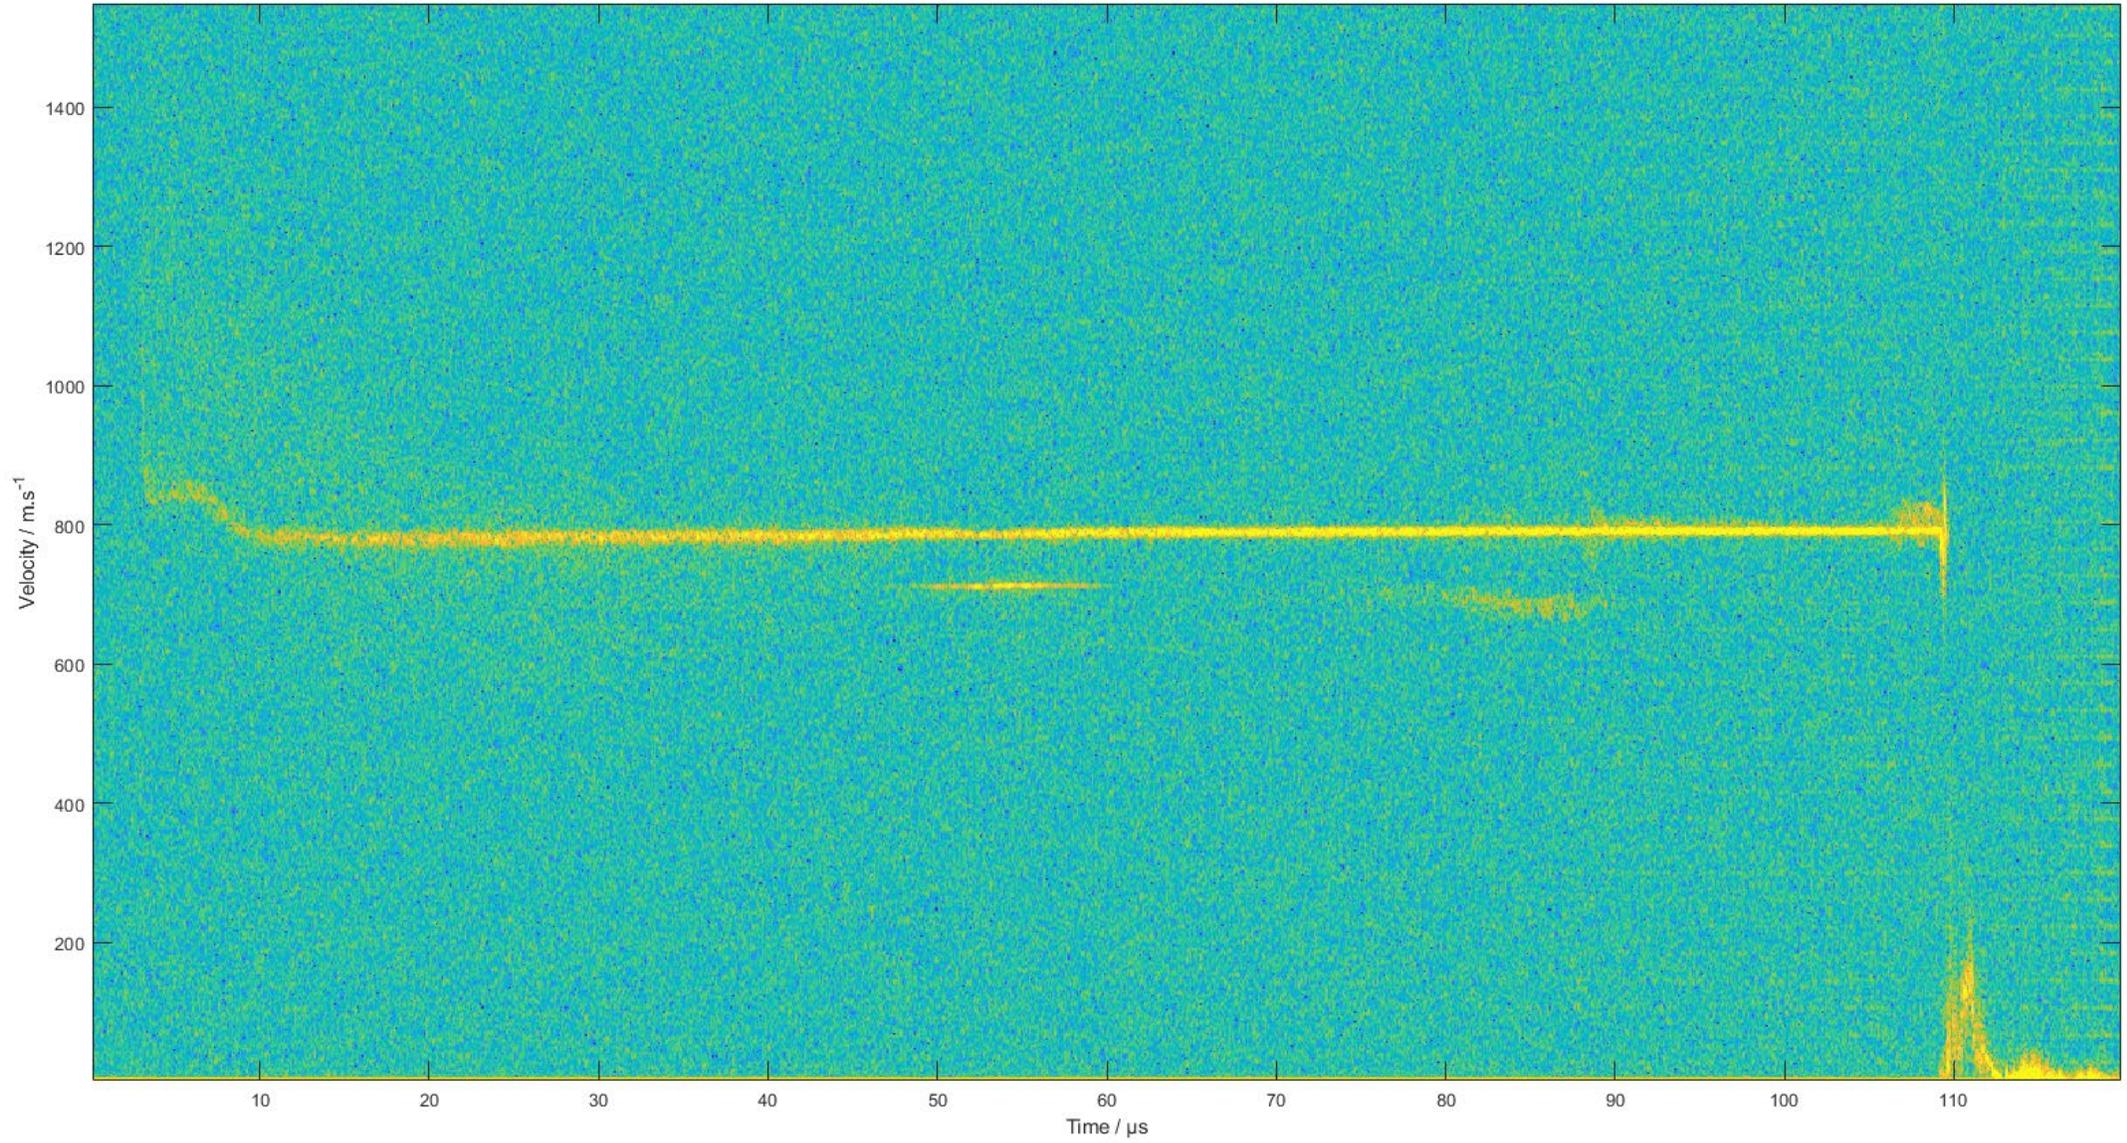

B. M. La Lone, B. R. Marshall, E. K. Miller, G. D. Stevens, W. D. Turley, L. R. Veaser; Simultaneous broadband laser ranging and photonic Doppler velocimetry for dynamic compression experiments. *Rev. Sci. Instrum.* 1 February 2015; 86 (2): 023112.

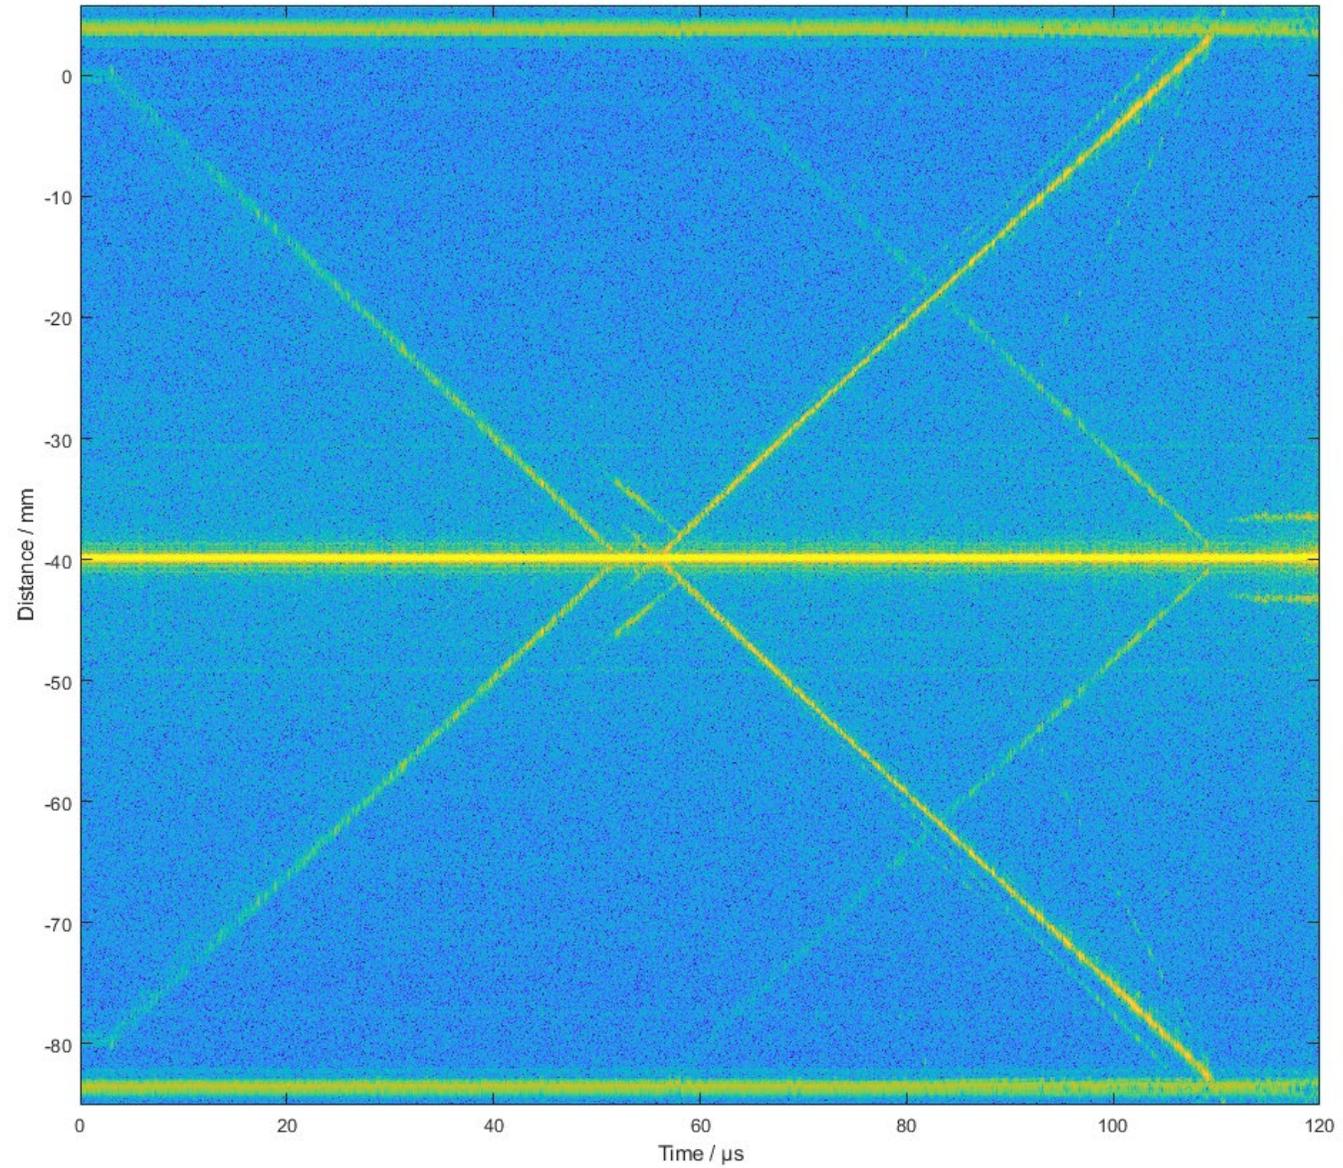

Experiment 1: Cu Disc

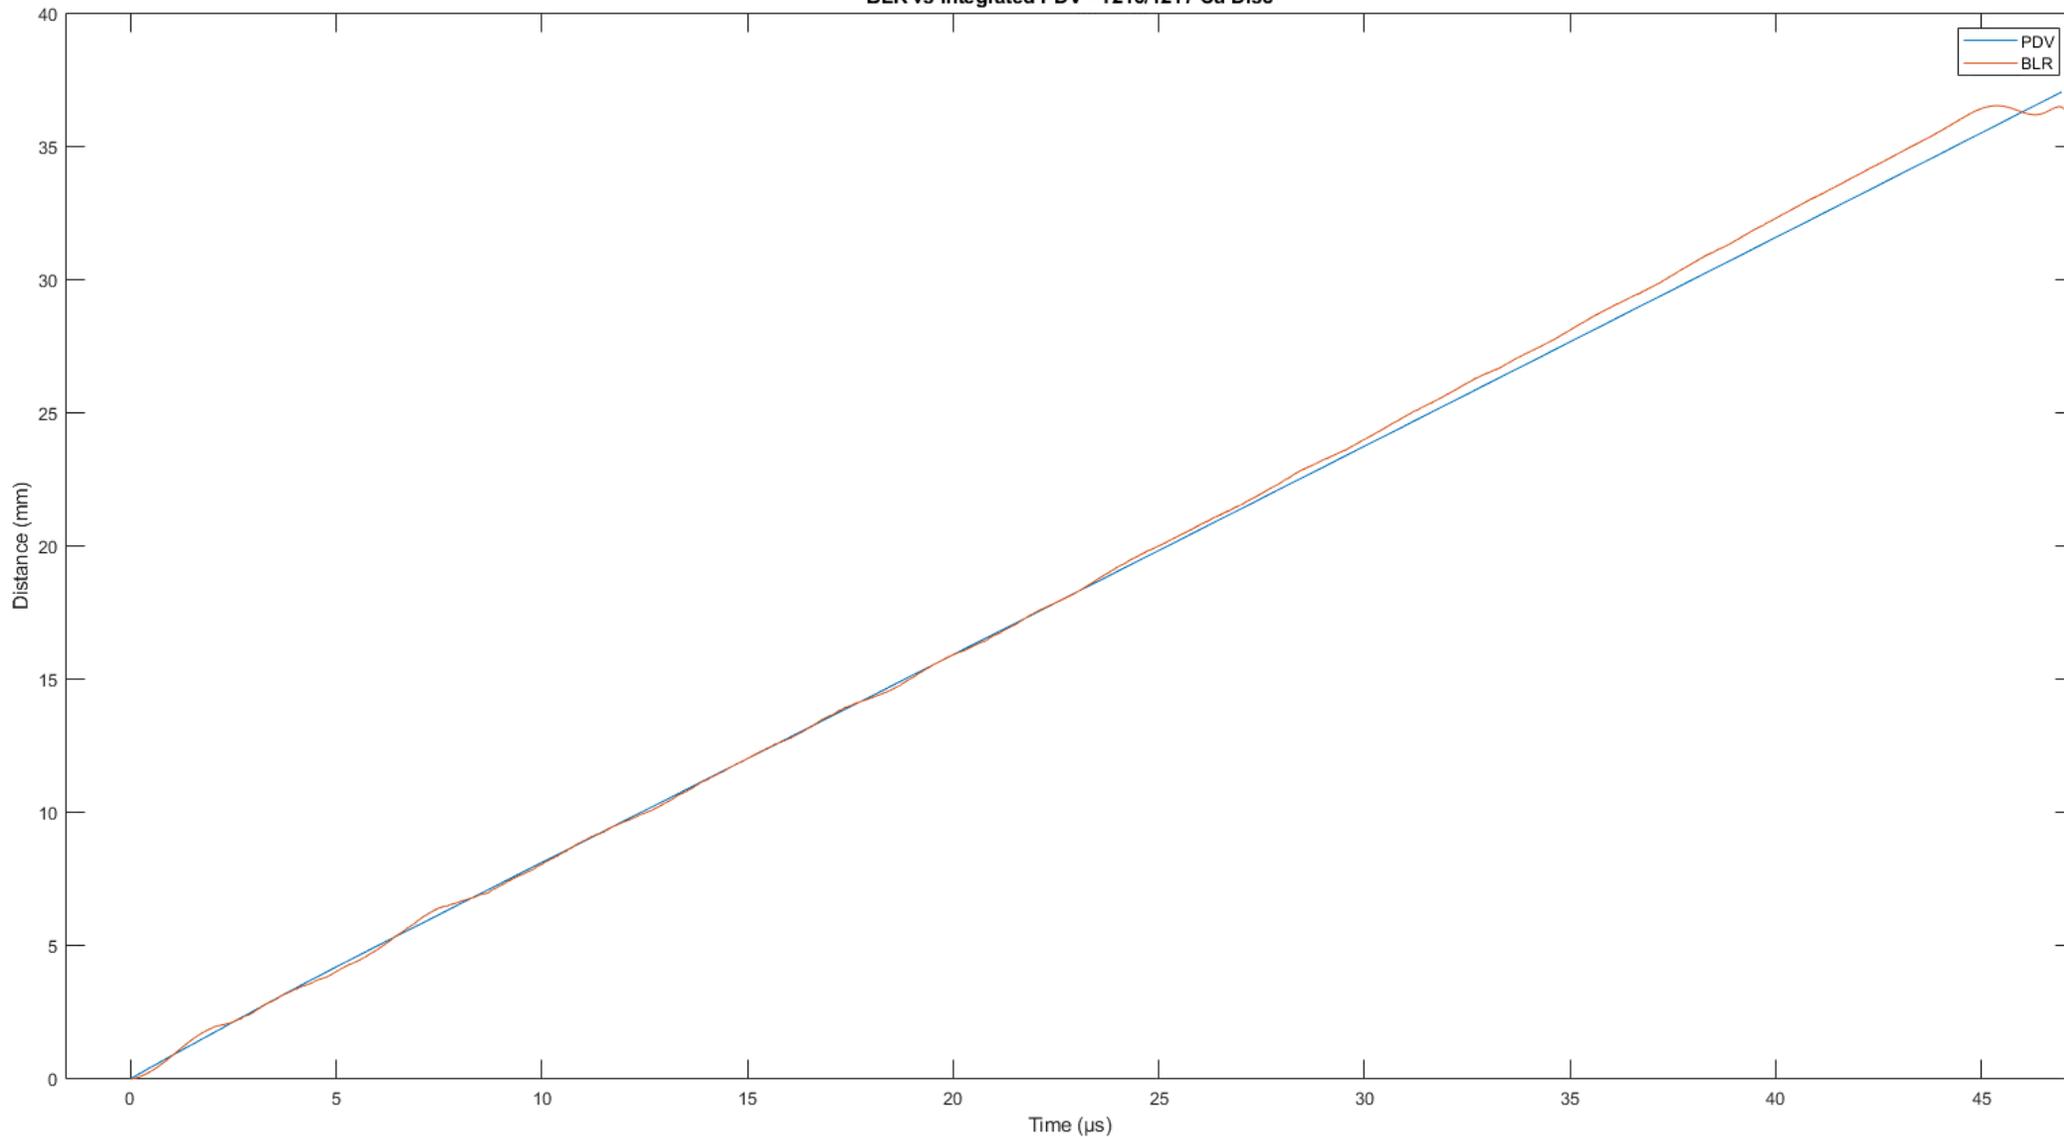

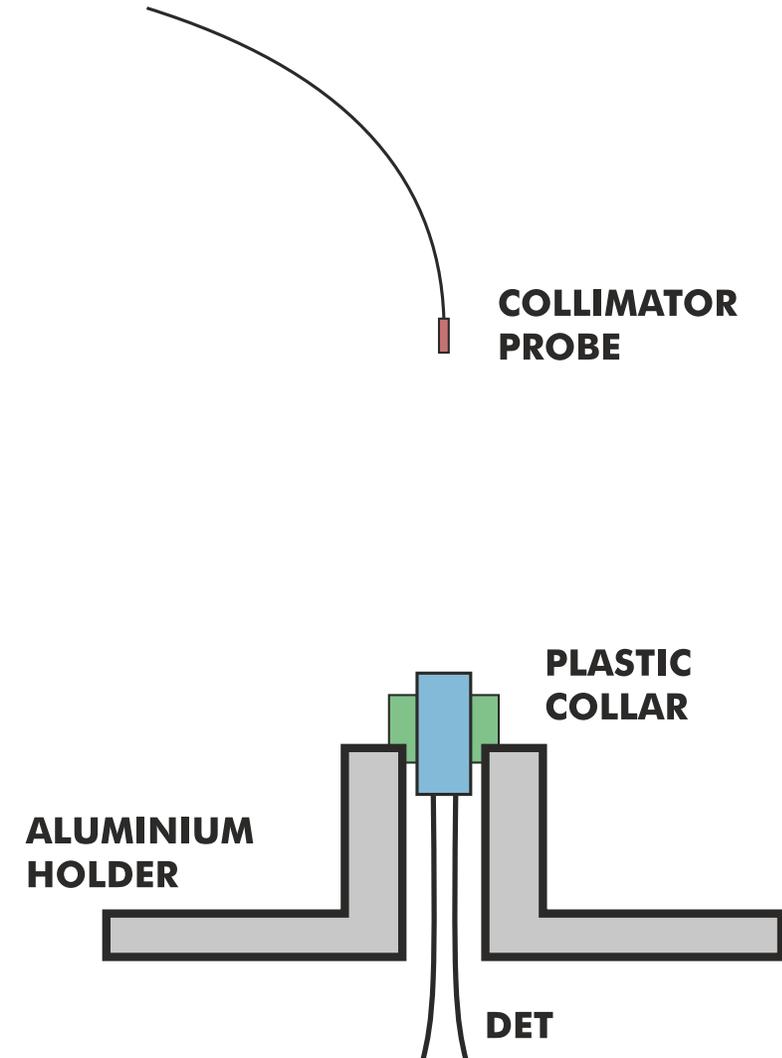

BLR vs Integrated PDV - T216/1217 Cu Disc

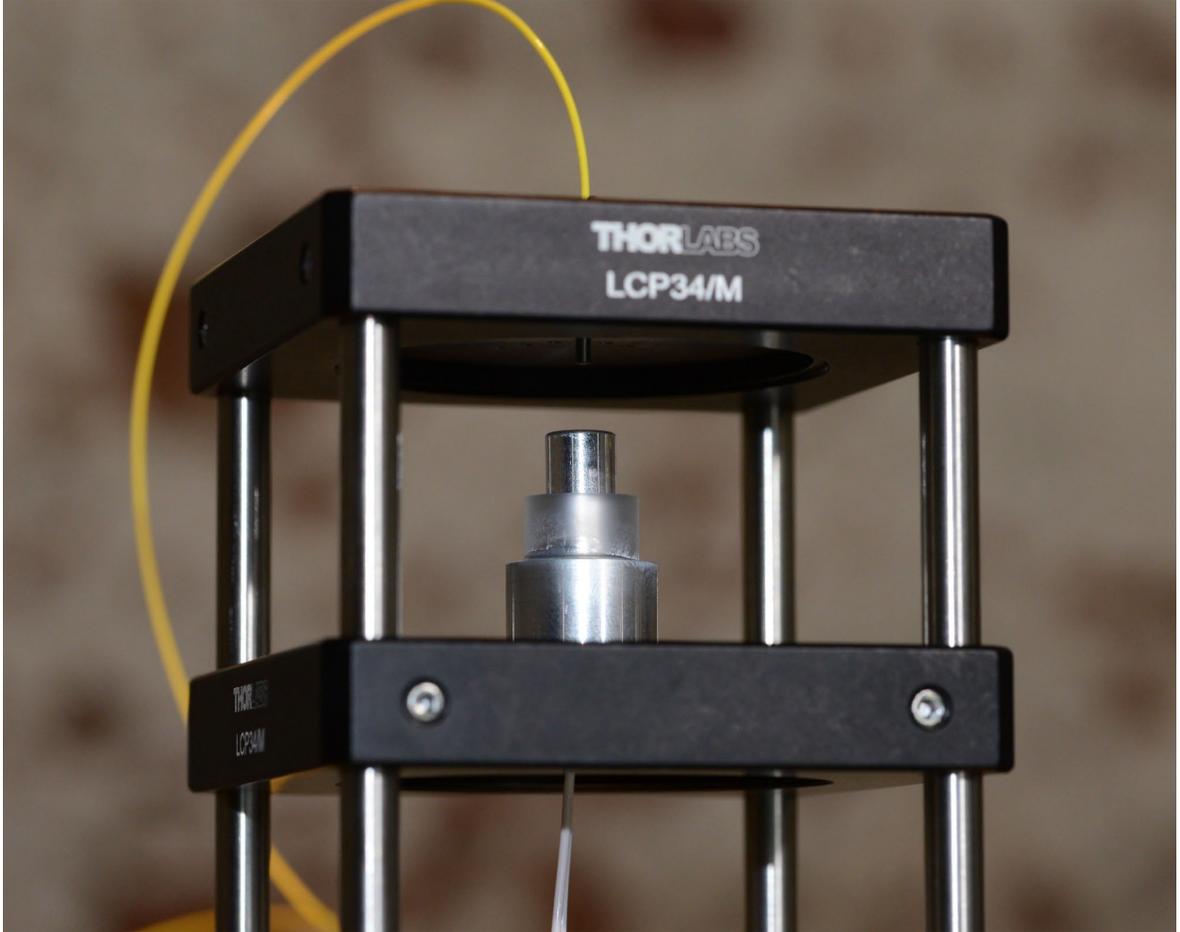

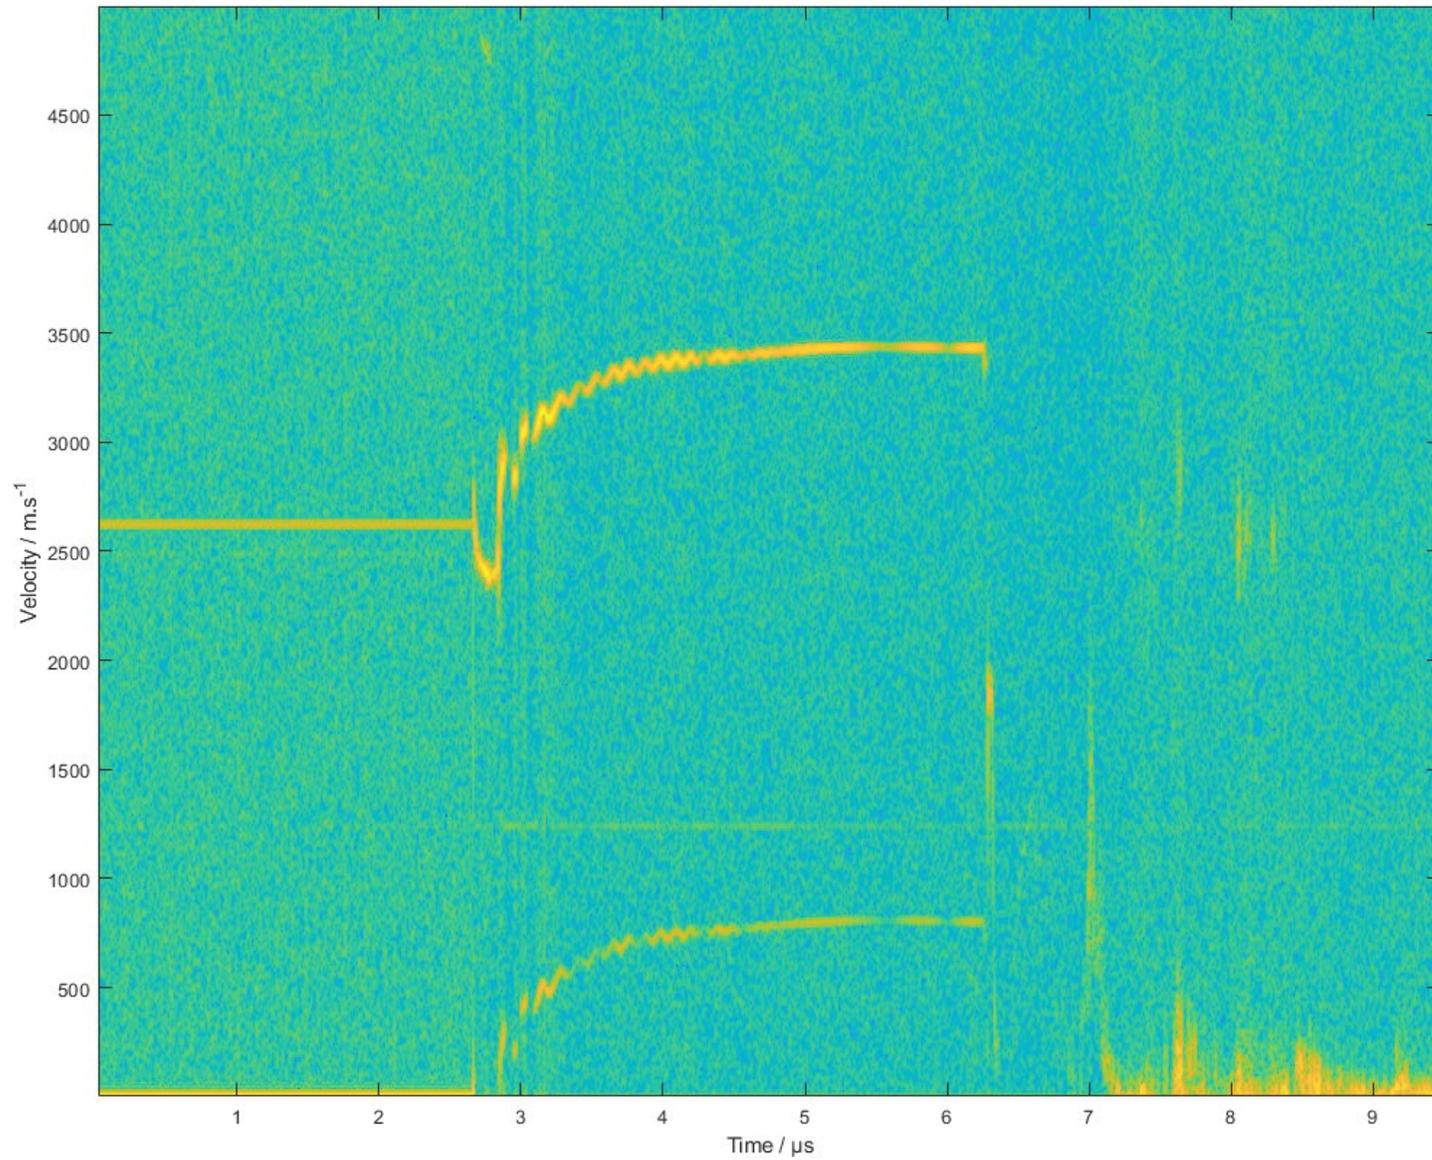

Experiment 2: Detonator

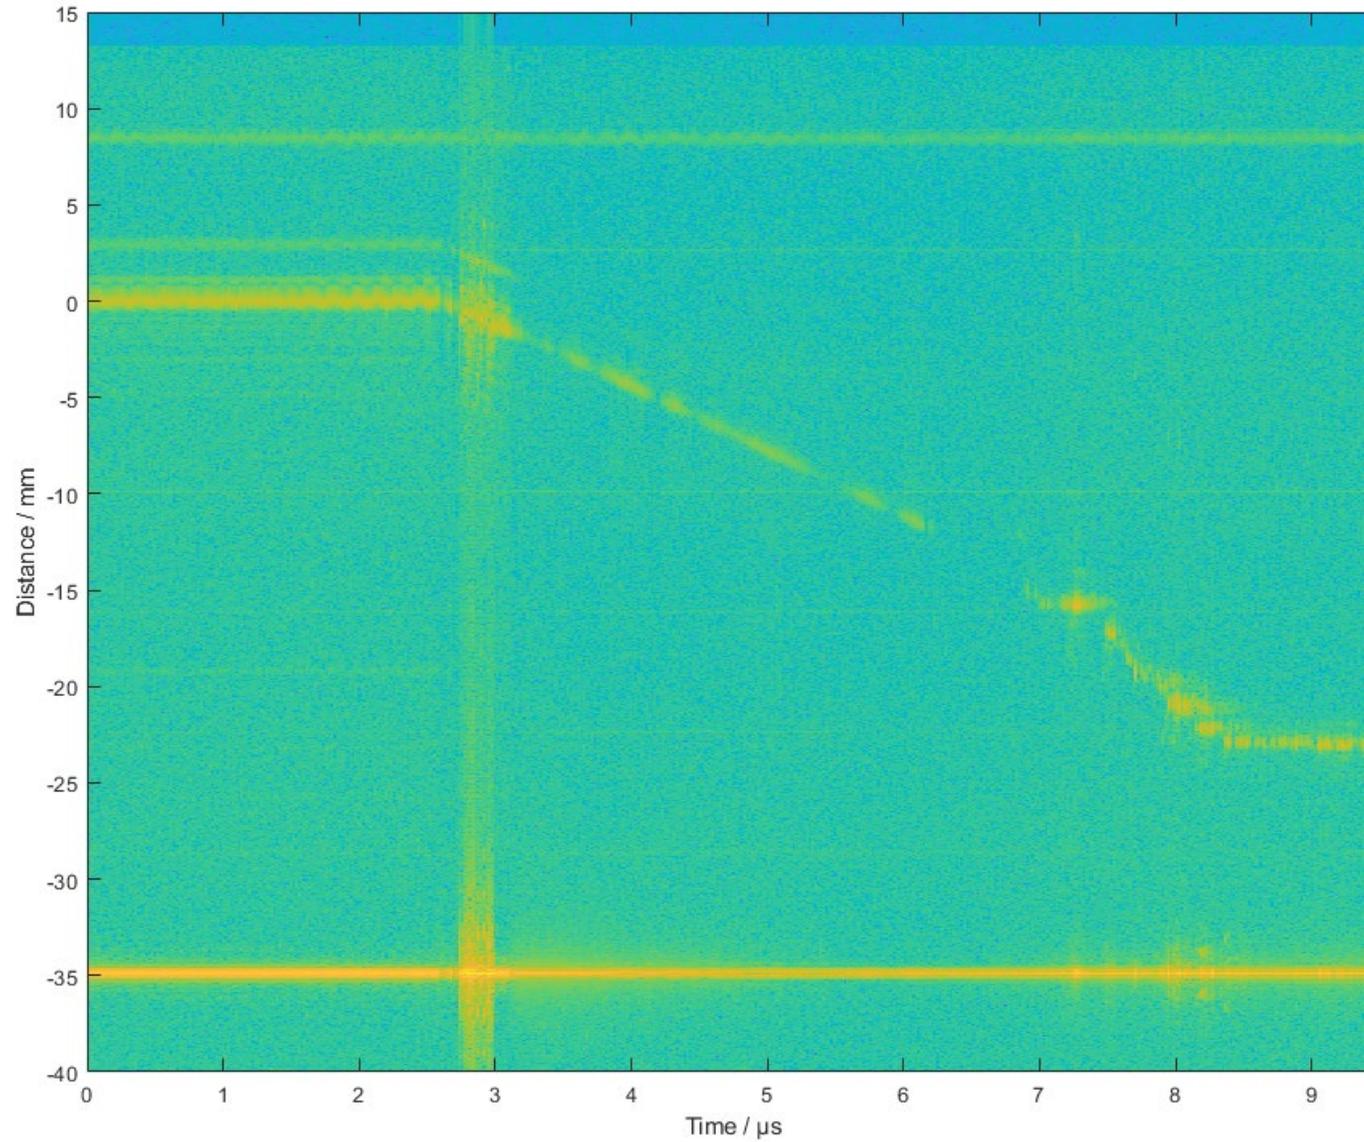

- Detonator glued into plastic collar
- Probe pointed at centre of detonator output

Experiment 2: Detonator

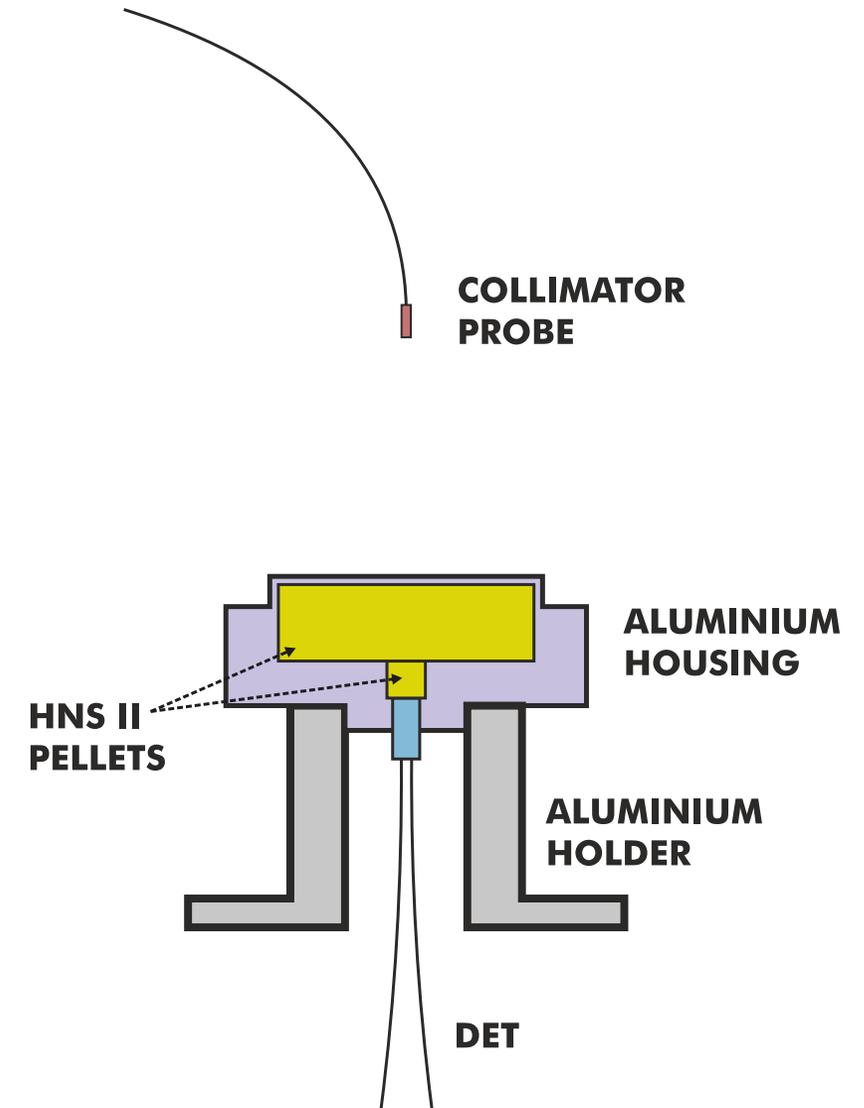

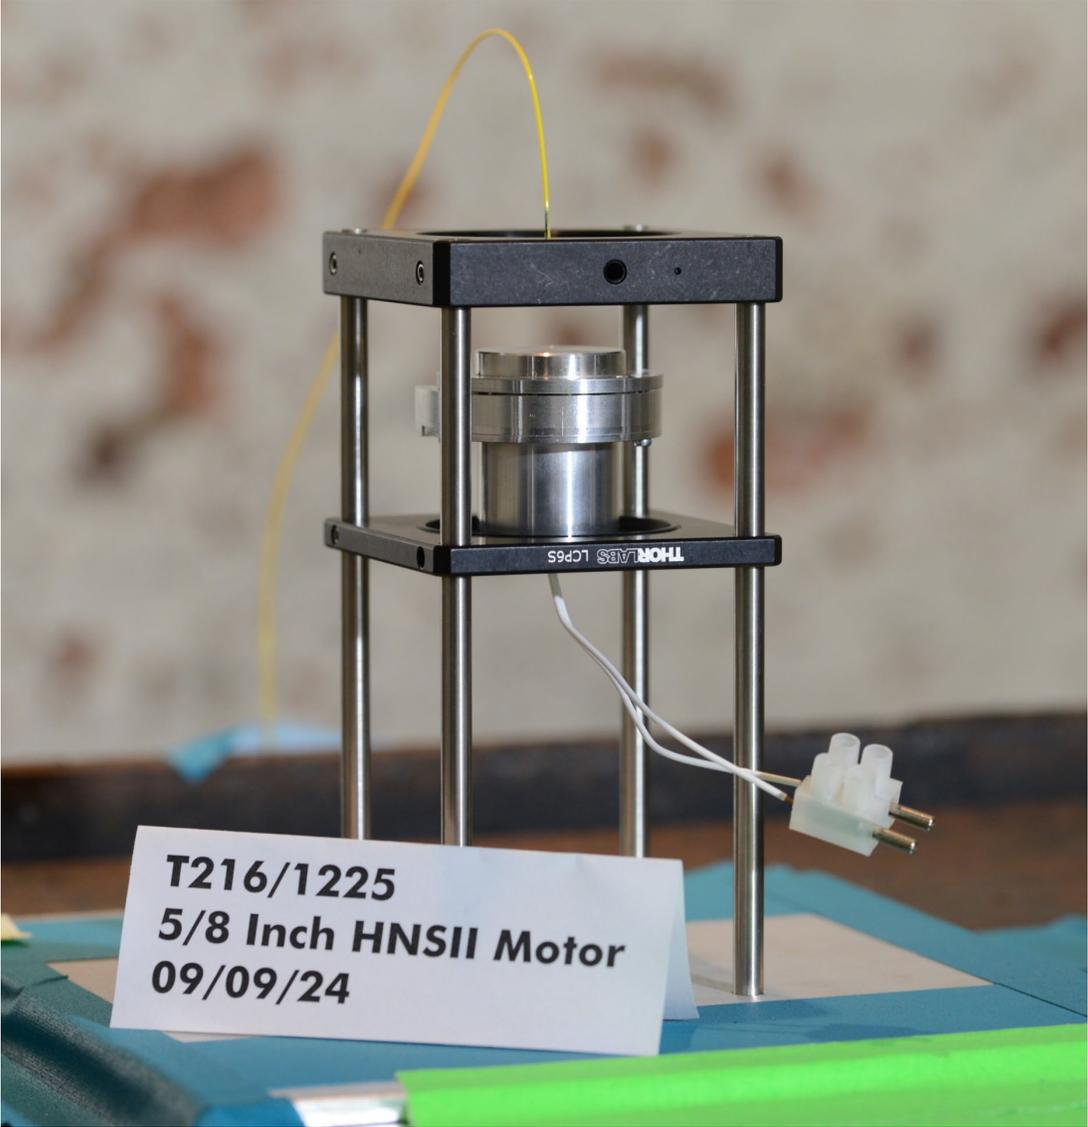

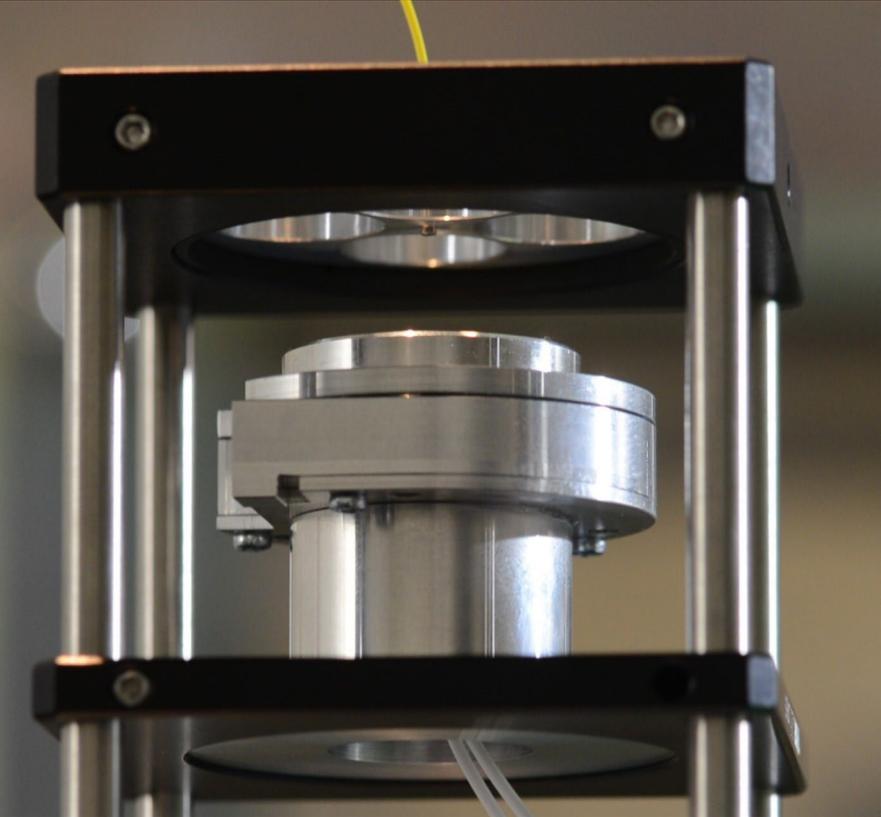

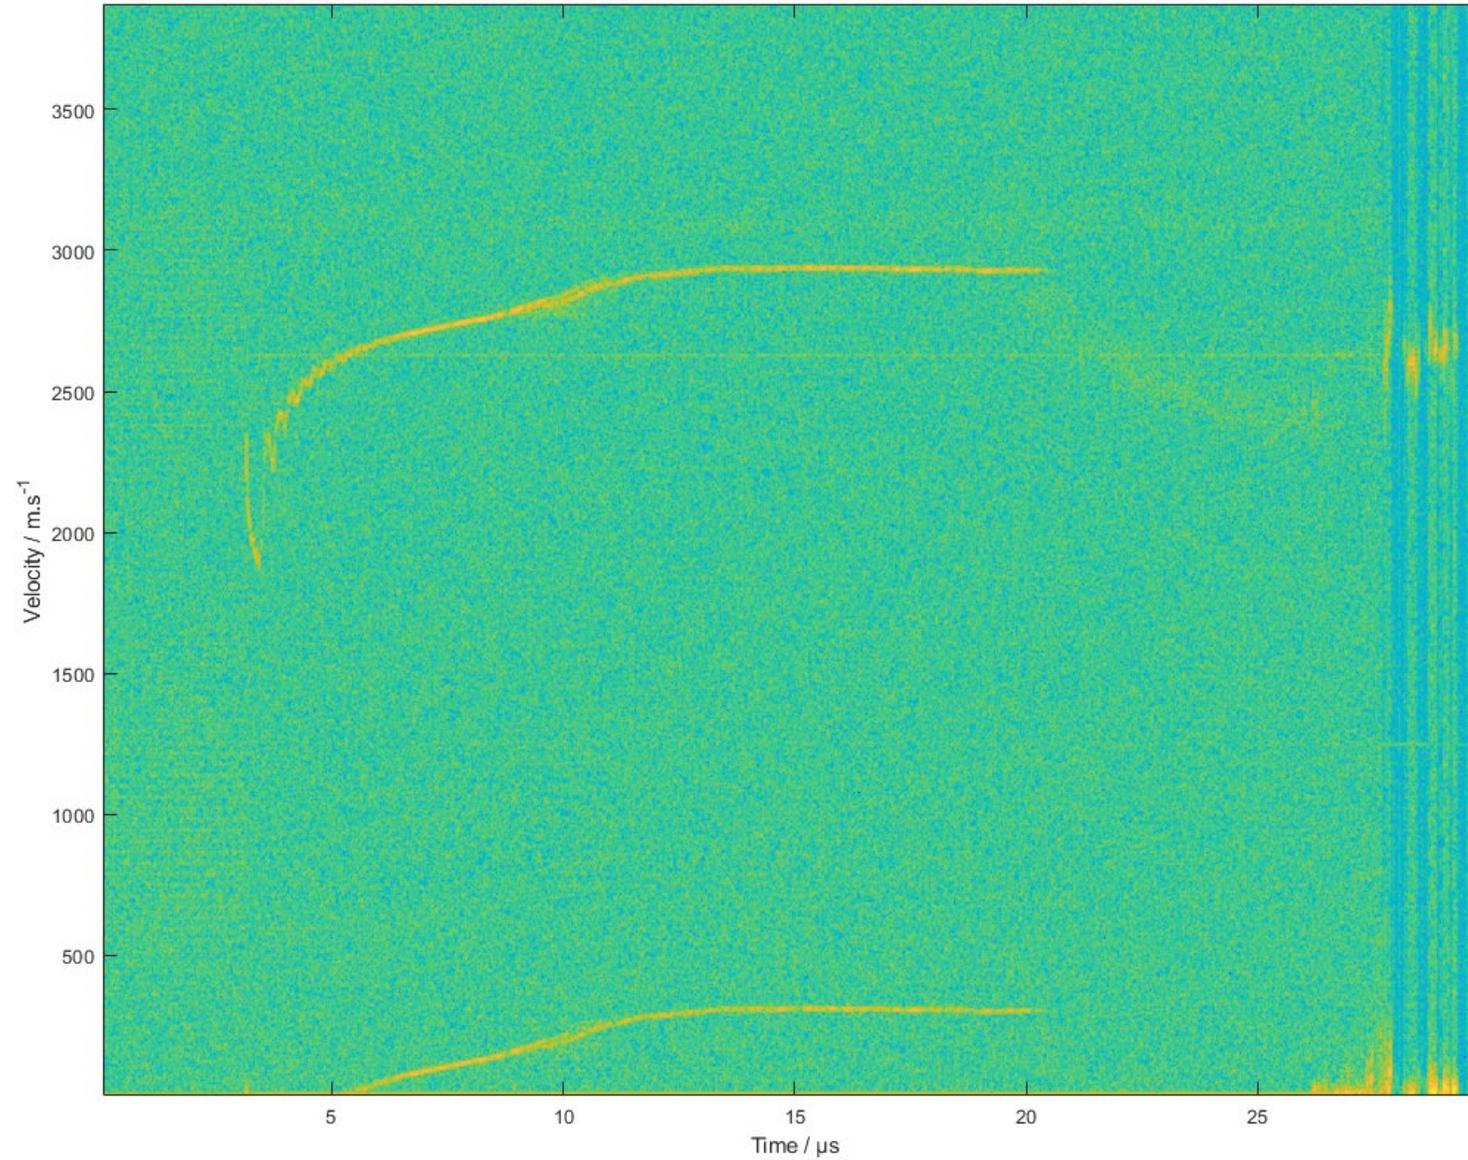

Experiment 3: Pellet Housing

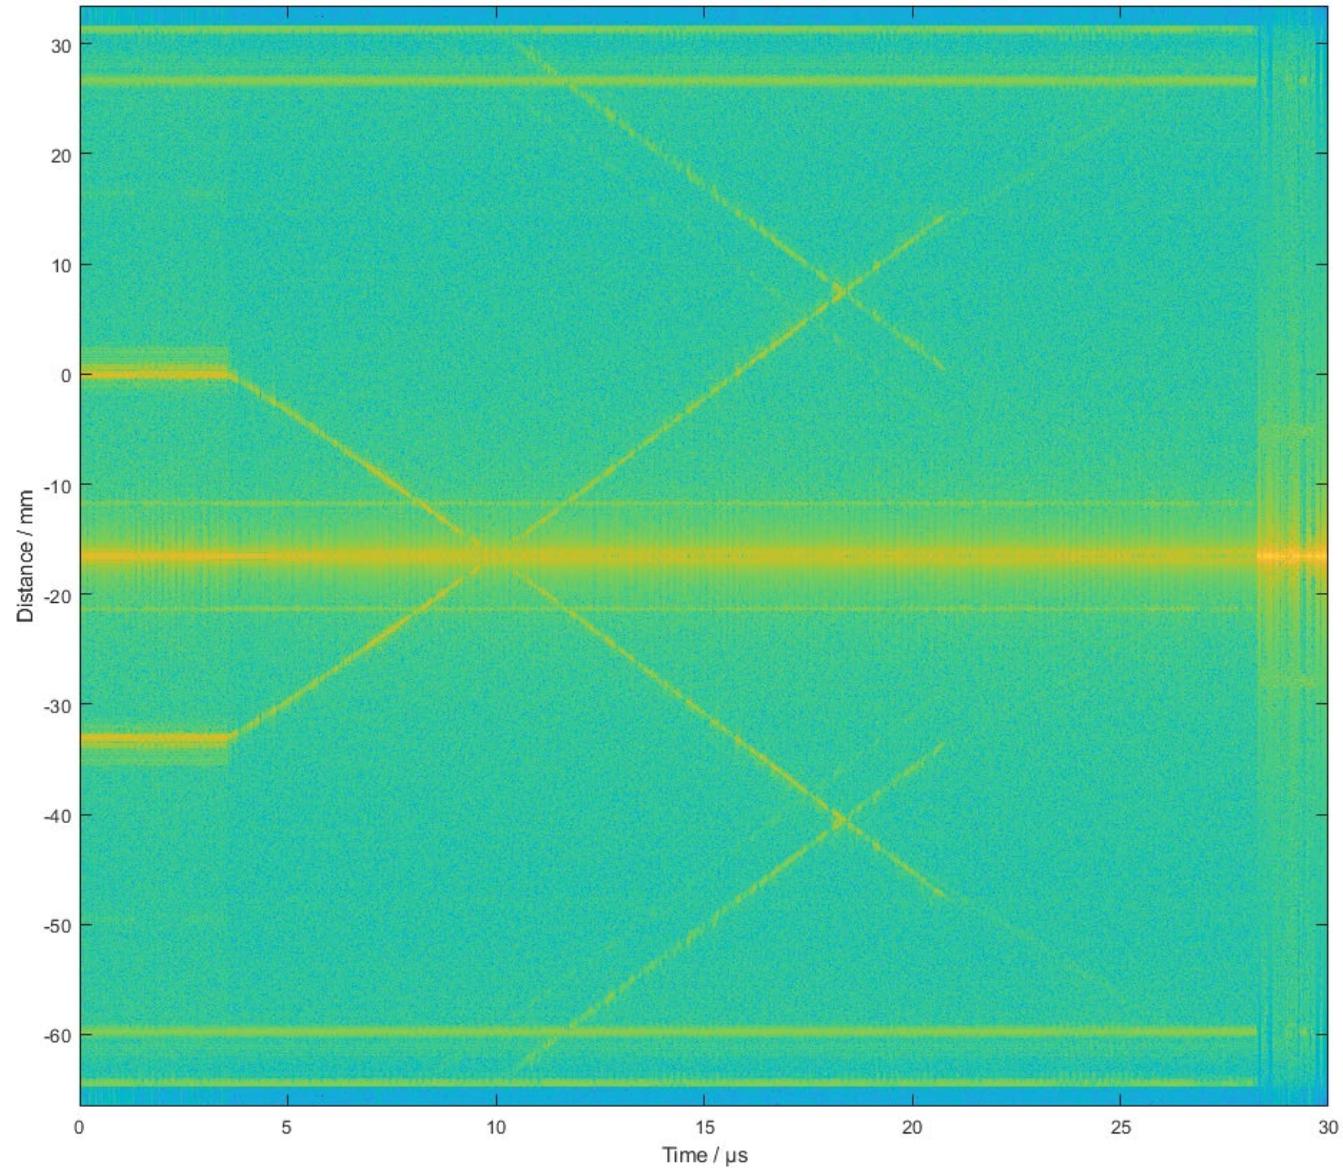

- 5/8" diameter Hexanitrostilbene II (HNS II) output pellet in thin aluminium housing
- 6 mm diameter intermediate pellet initiated by detonator

Experiment 3: Pellet Housing

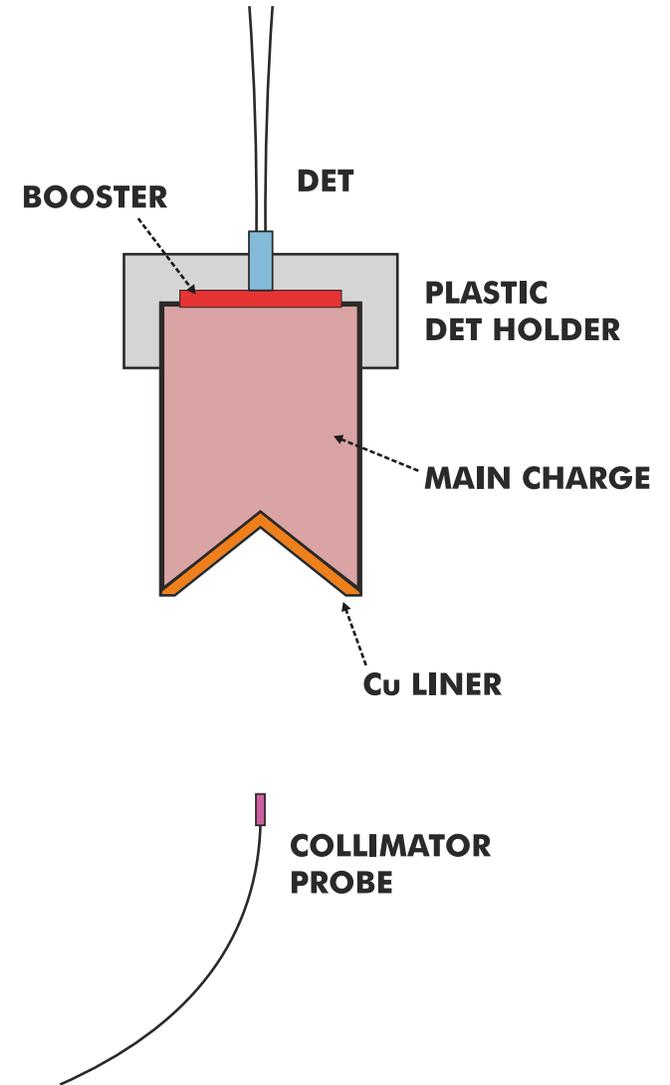

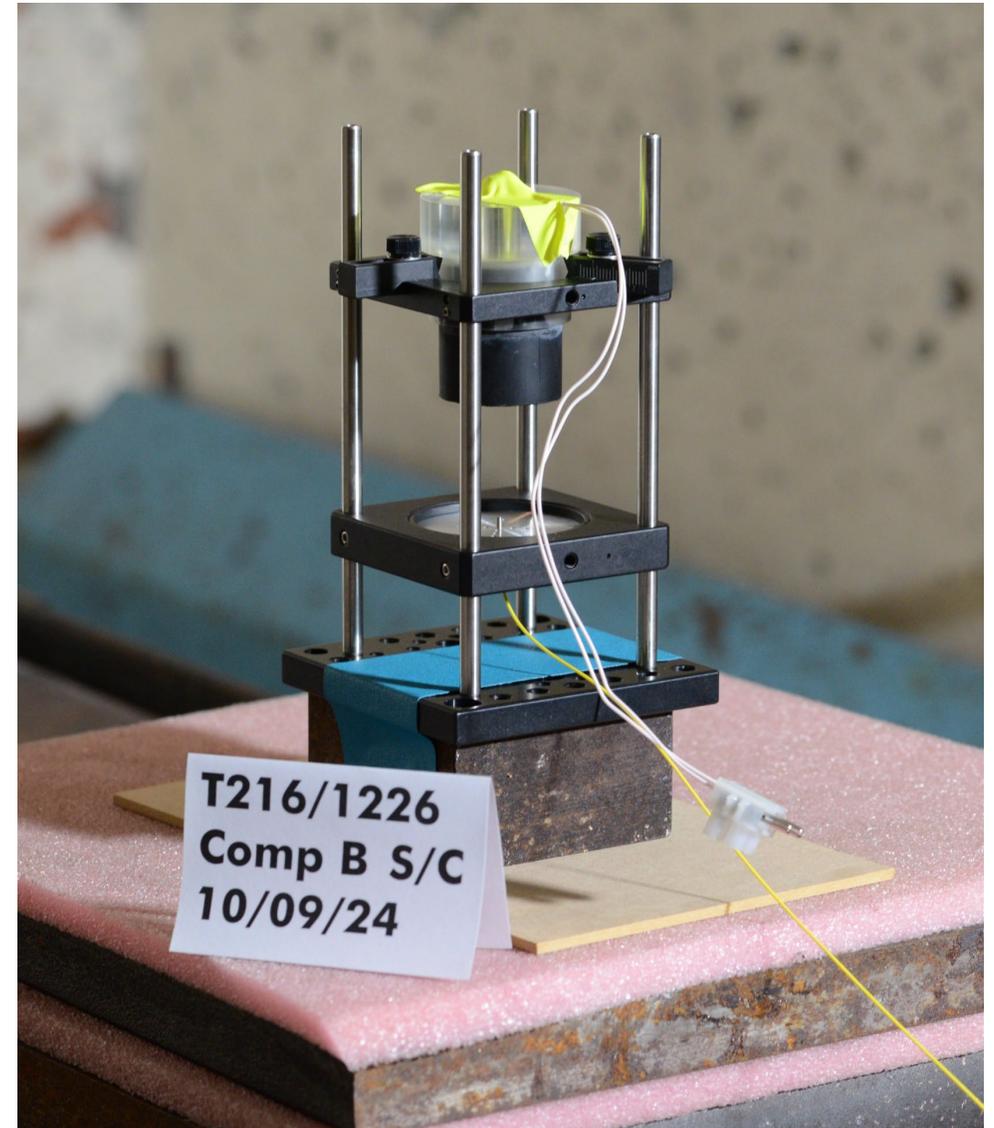

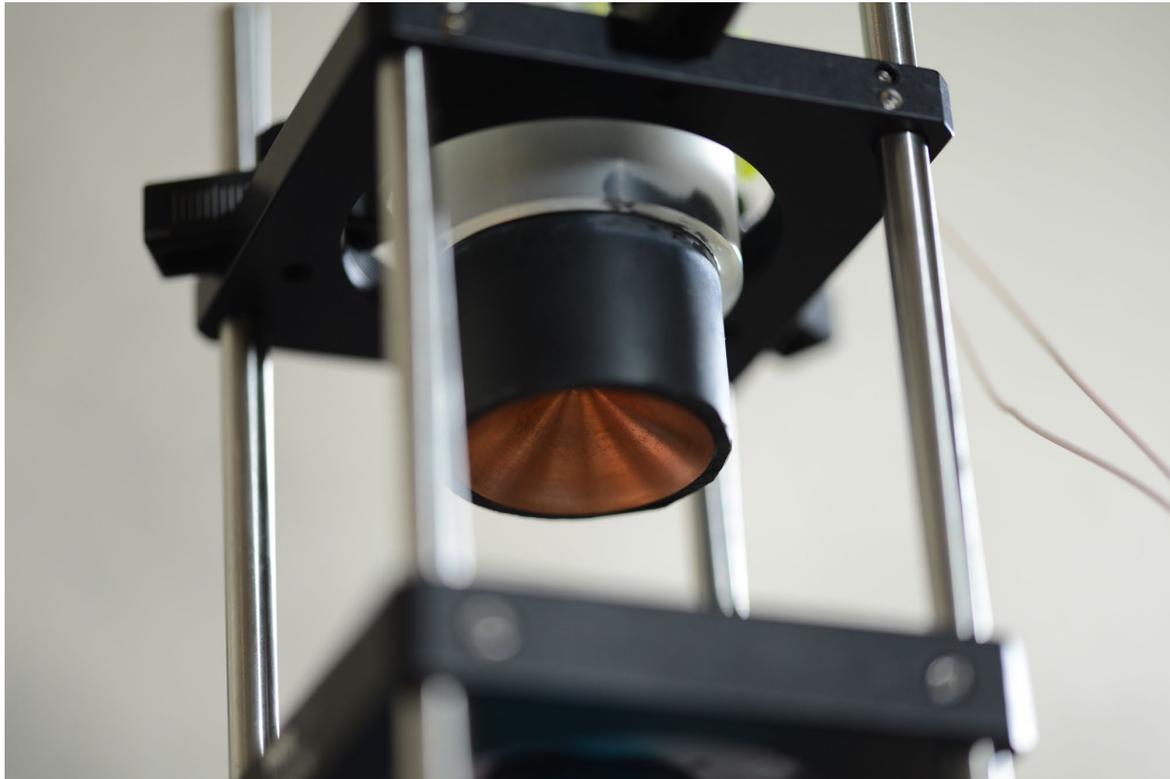

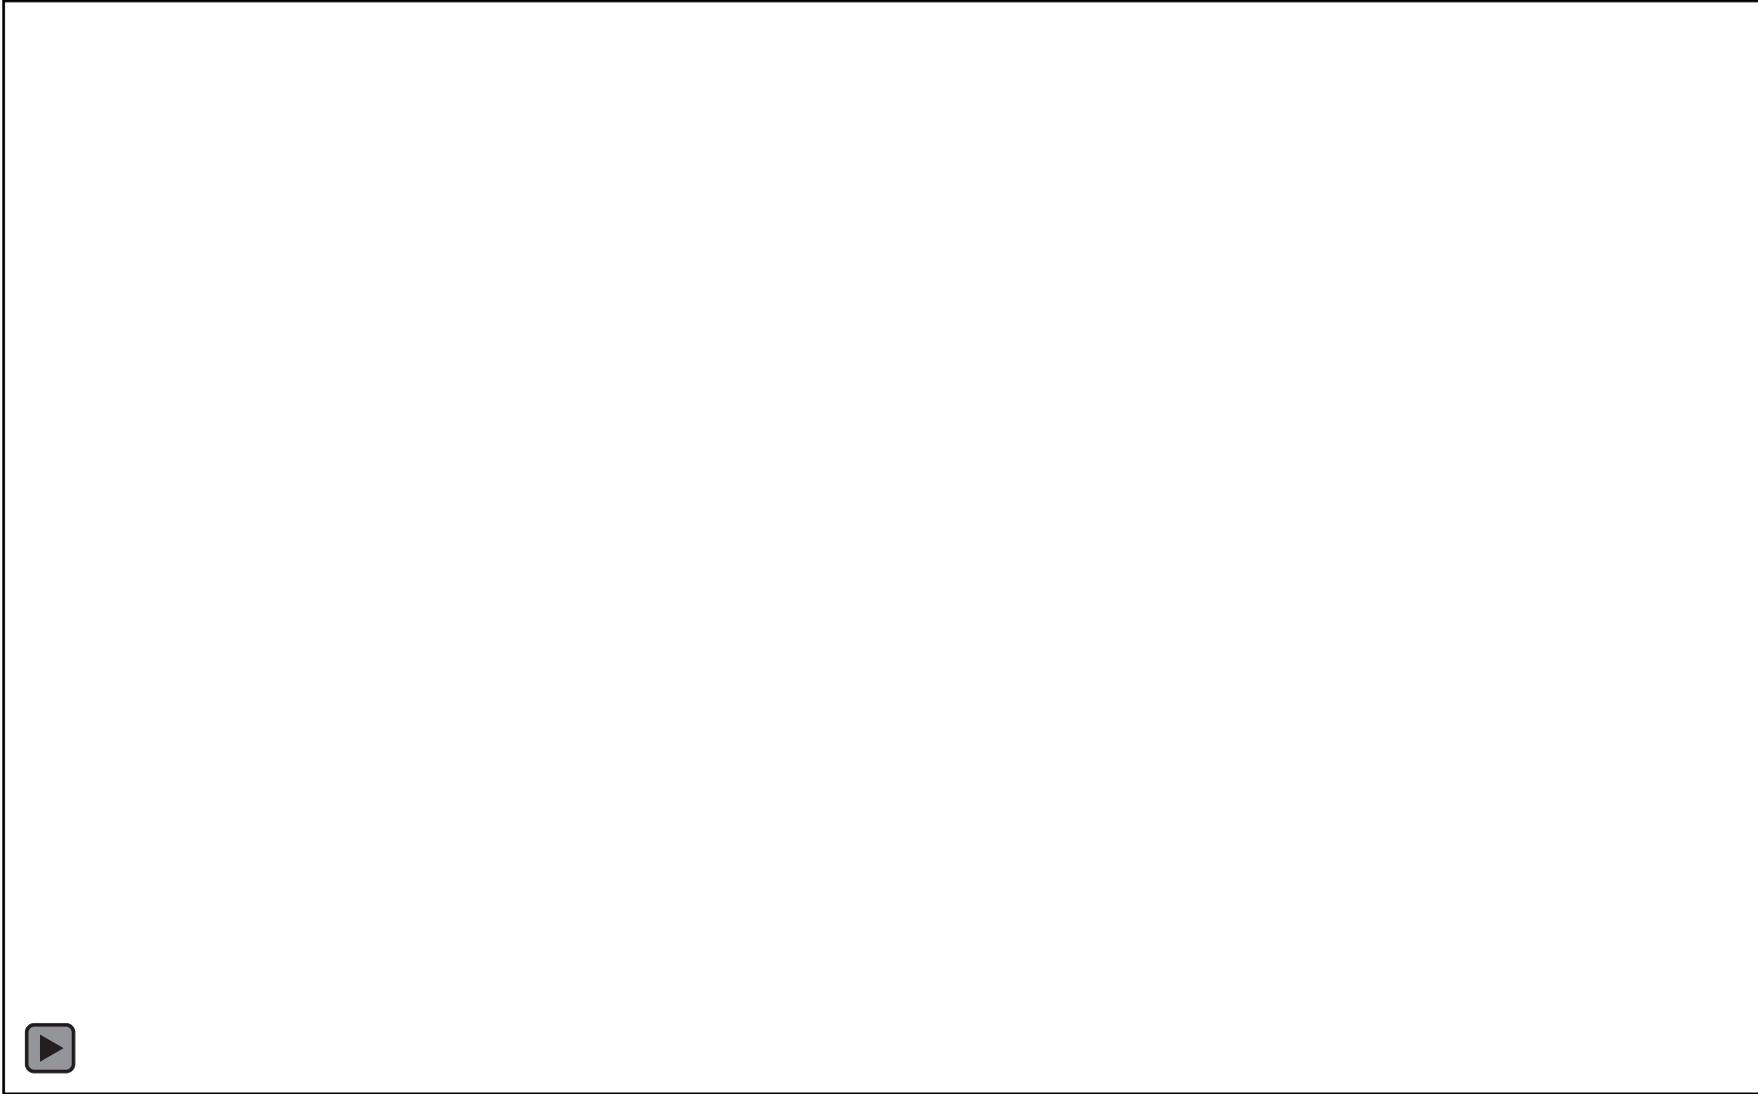

Experiment 4: Shaped Charge

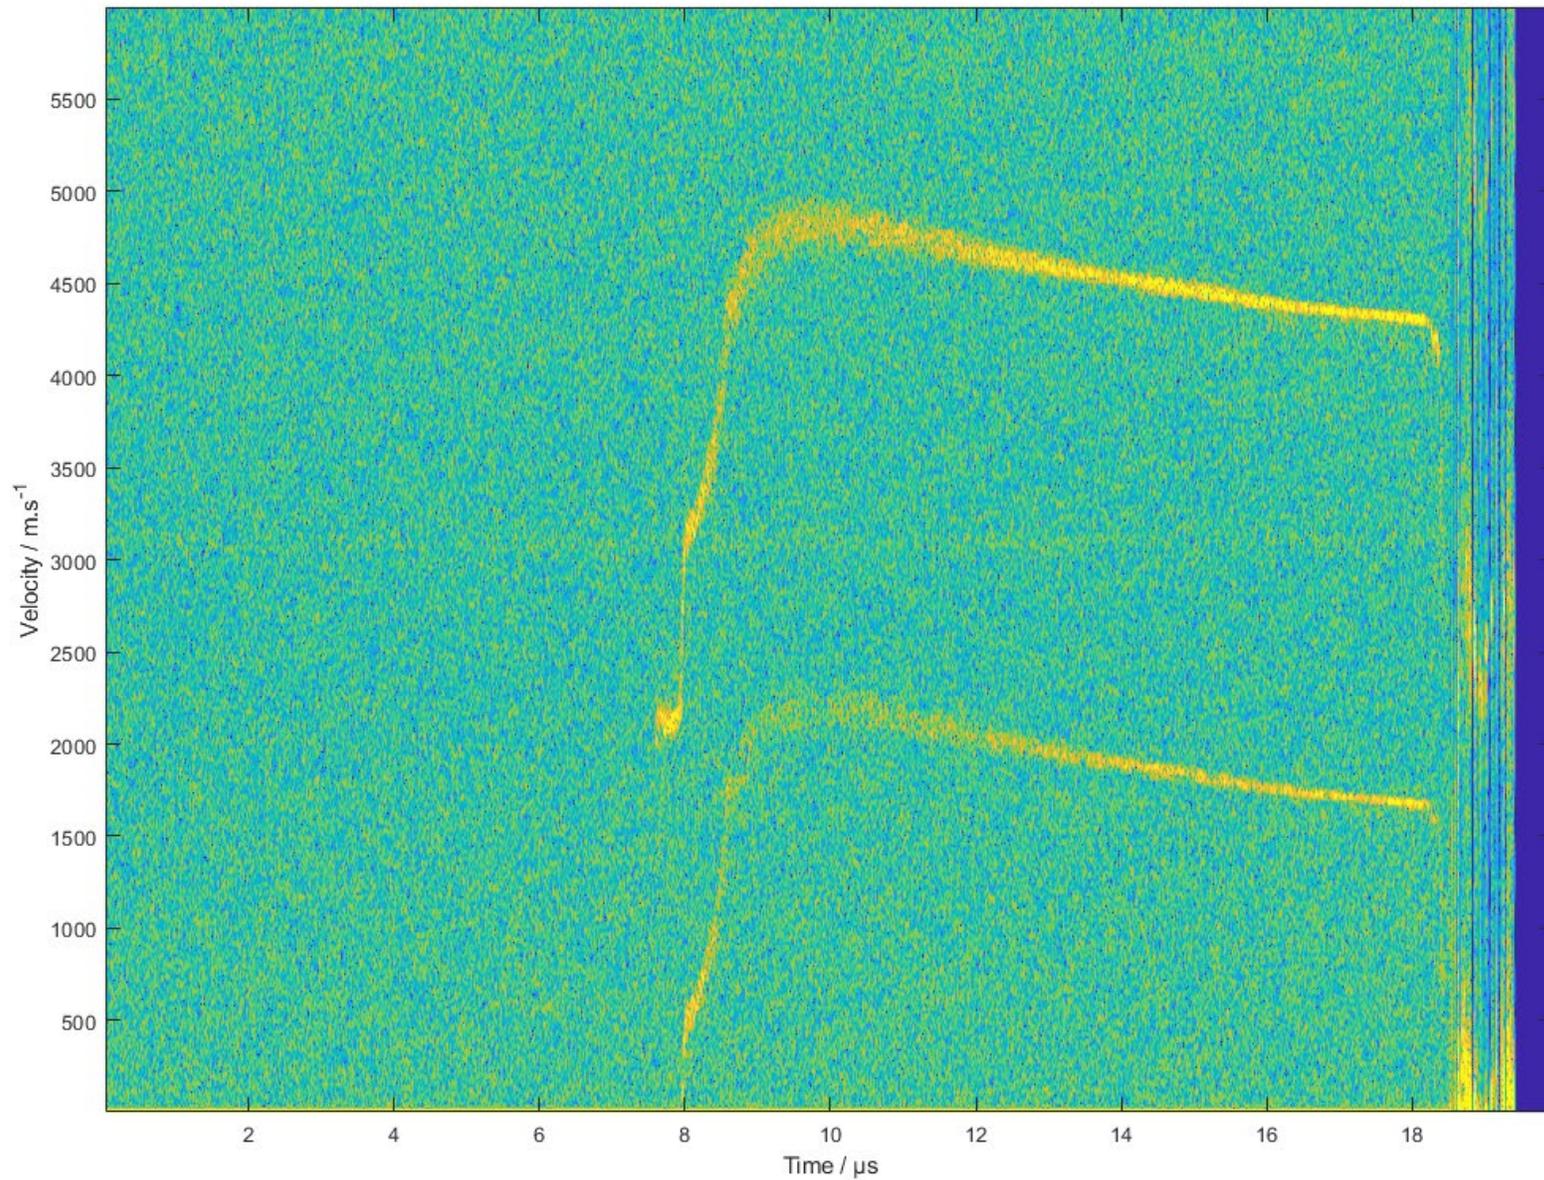

- 30 mm diameter shaped charge
- Conical copper liner
- Composition B (RDX/TNT) cast fill
- End-initiating detonator with PETN sheet explosive booster
- Probe pointed at liner apex, along charge axis

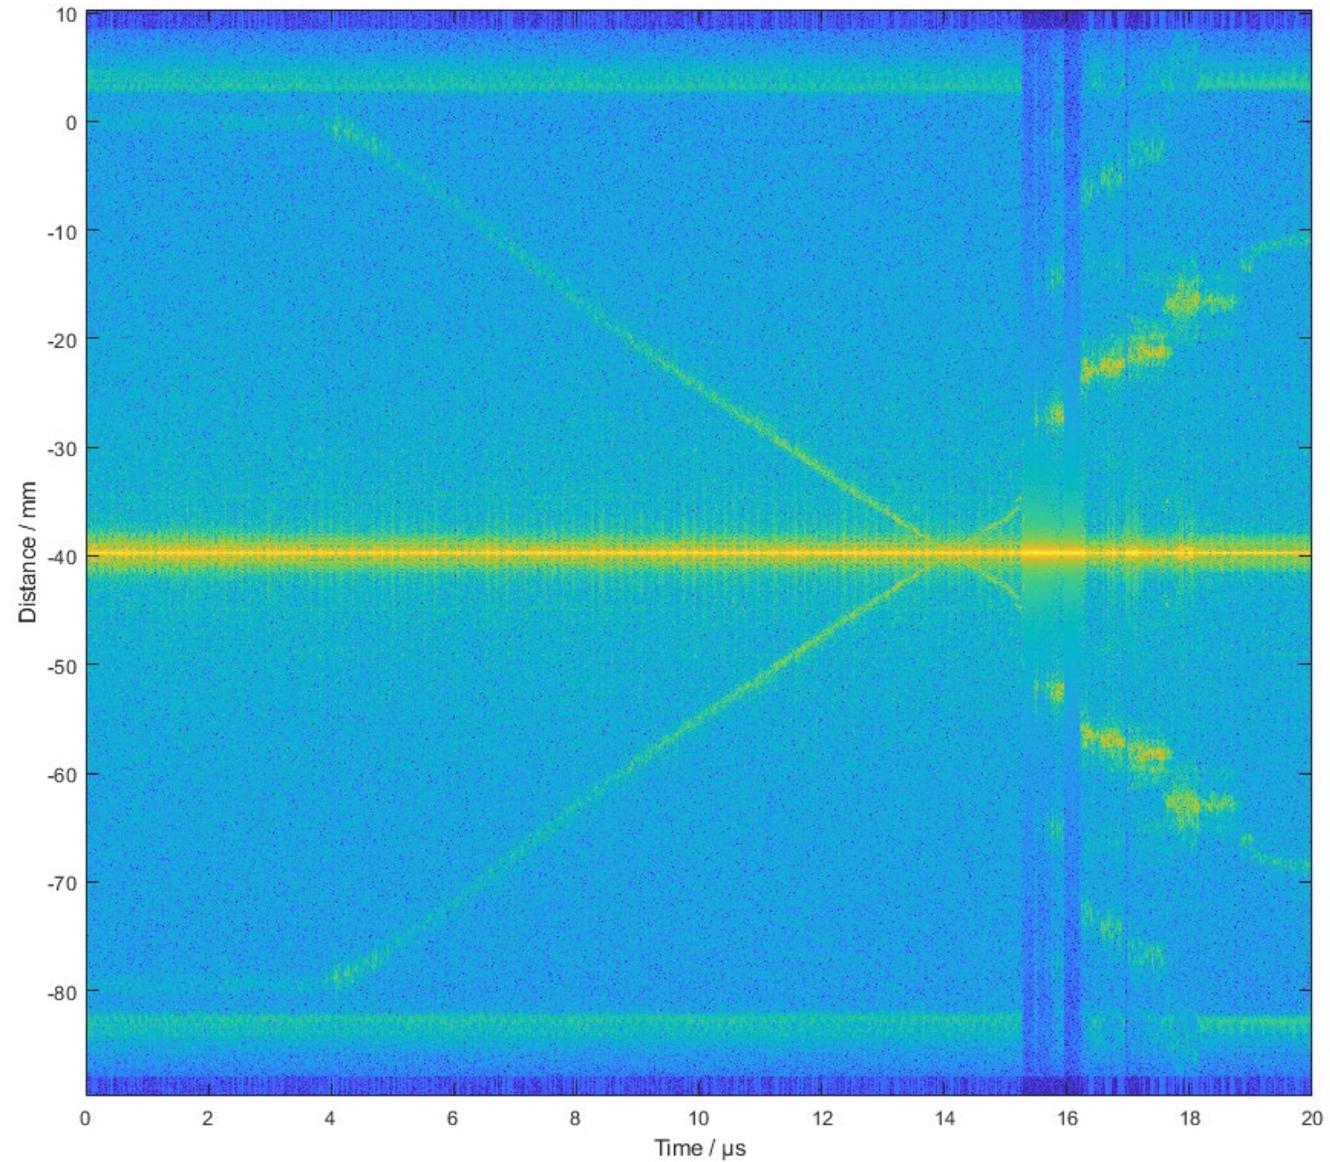

Experiment 4: Shaped Charge

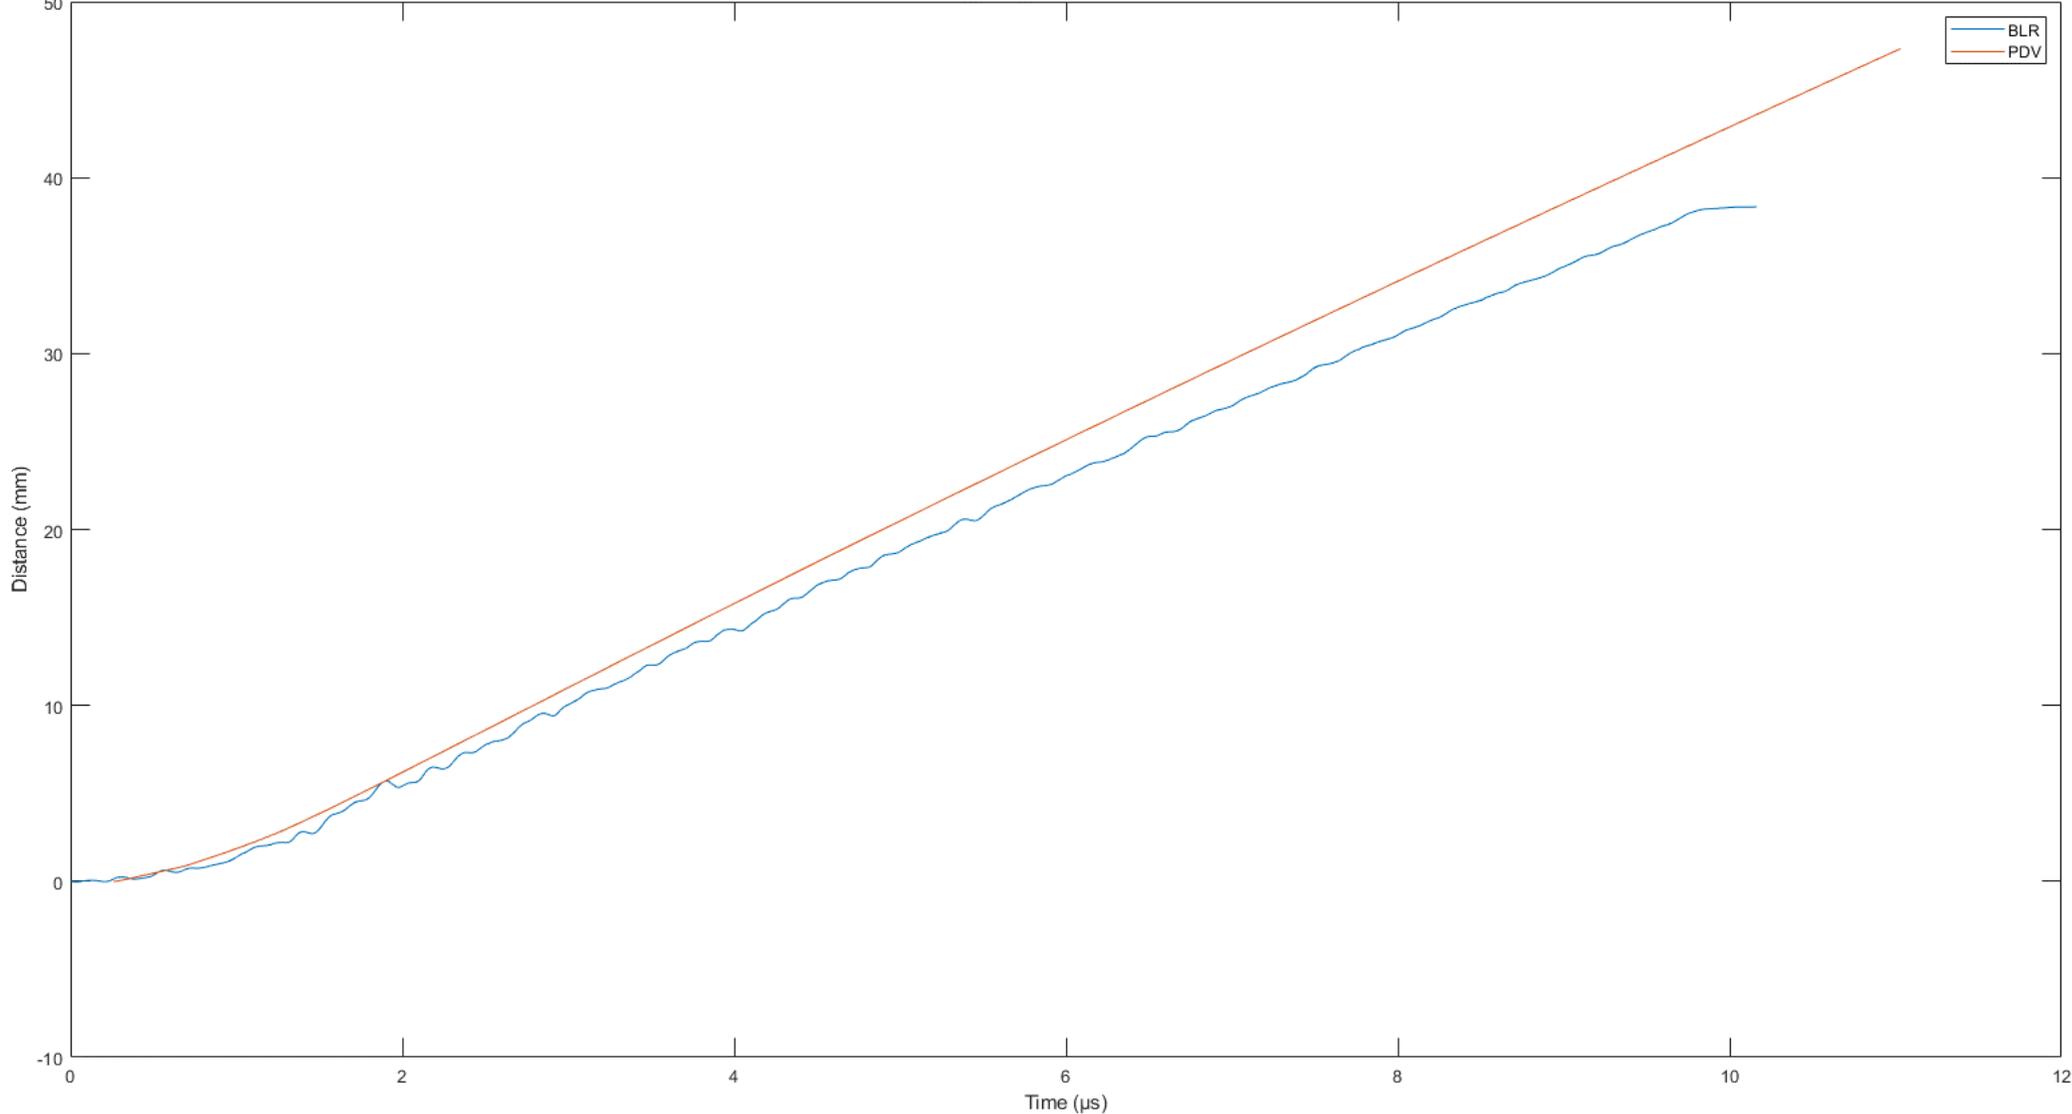

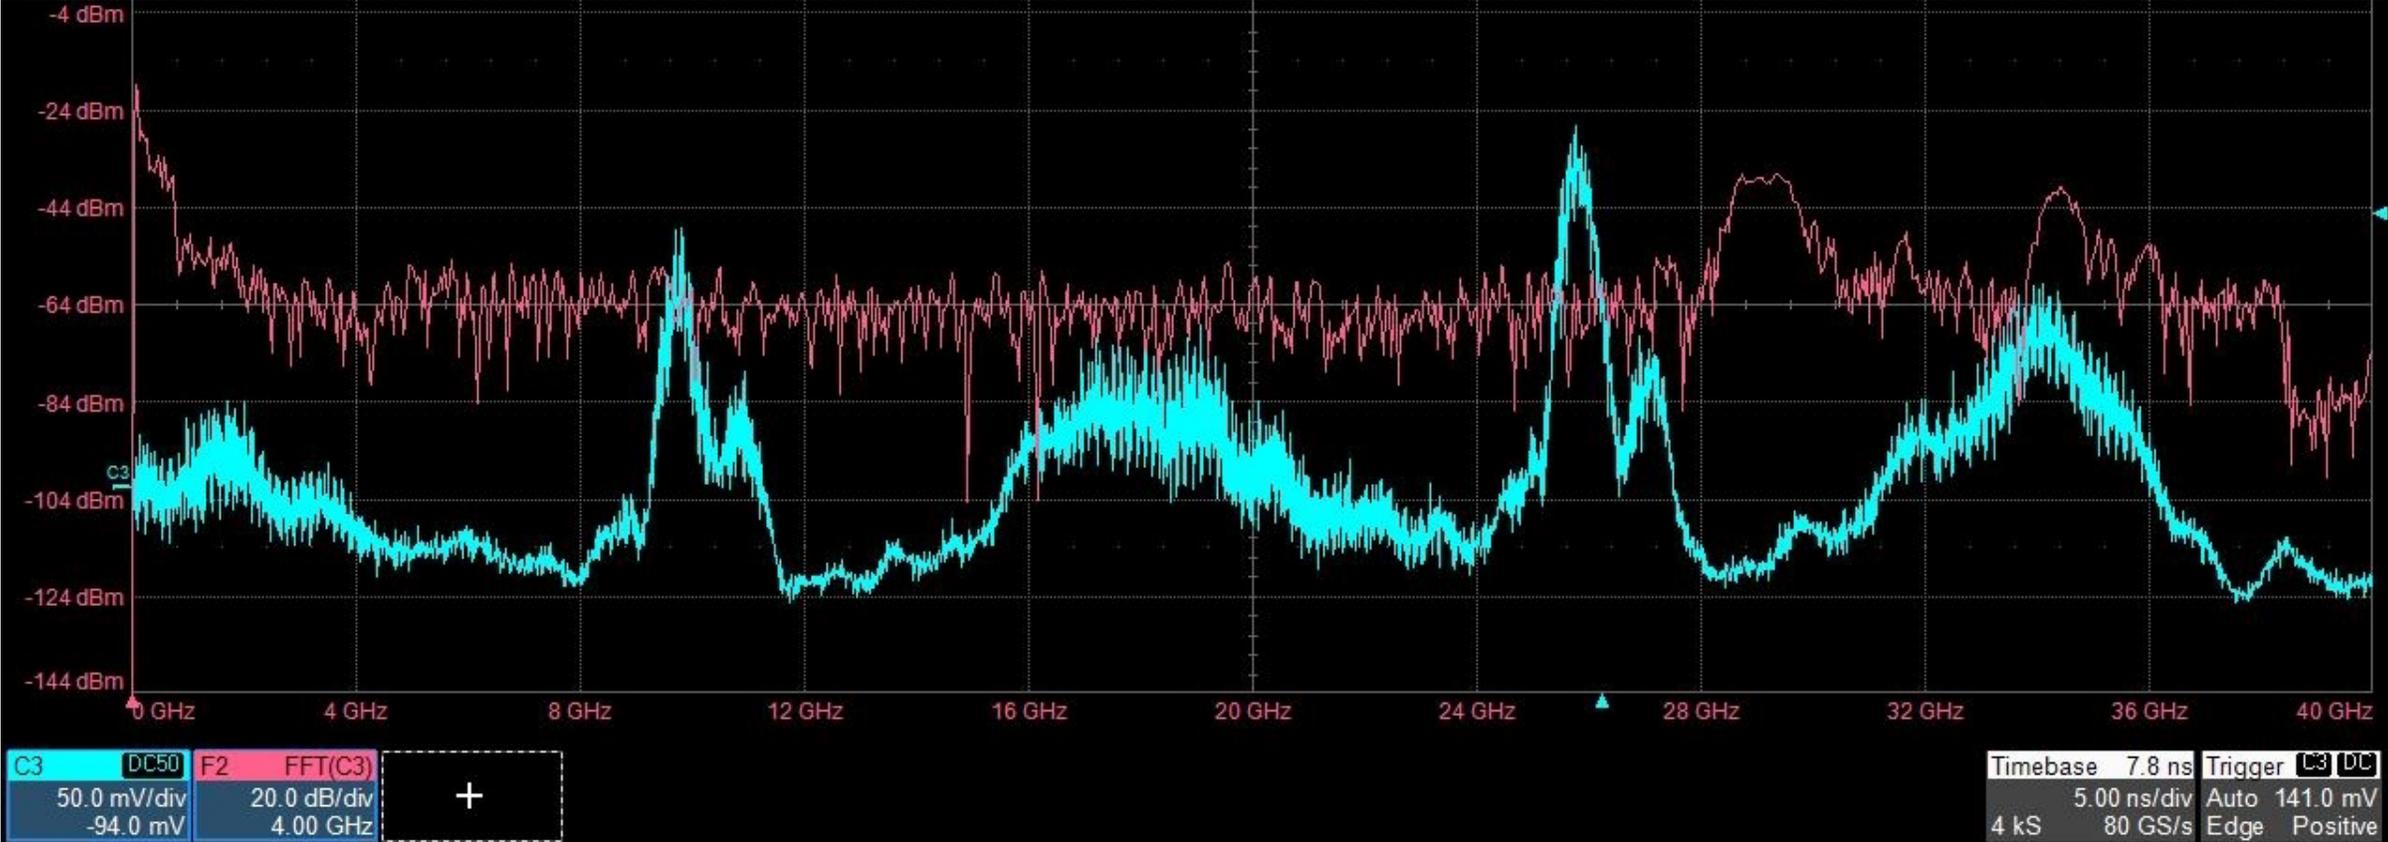

BLR vs Integrated PDV - T216/1226 30 mm Comp B Shaped Charge

Issues and Improvements – BLR

- Implement polarisation control to improve SNR
- Characterise seed laser pump current dependent wavelength shift using spectrometer – this is seen on digitiser FFT
 - Filters are for 1533 – 1564 nm pass band
- Add a pulse picker
 - Reduce setup time by making correlating pulses easier when single-triggered
 - Allow reduced rep rate during experiments
 - At 50 MHz this system is close to overlapping pulses
- Replace EDFA with Raman amplifier scheme using DCF – benefits?

Issues and Improvements – BLR SNR

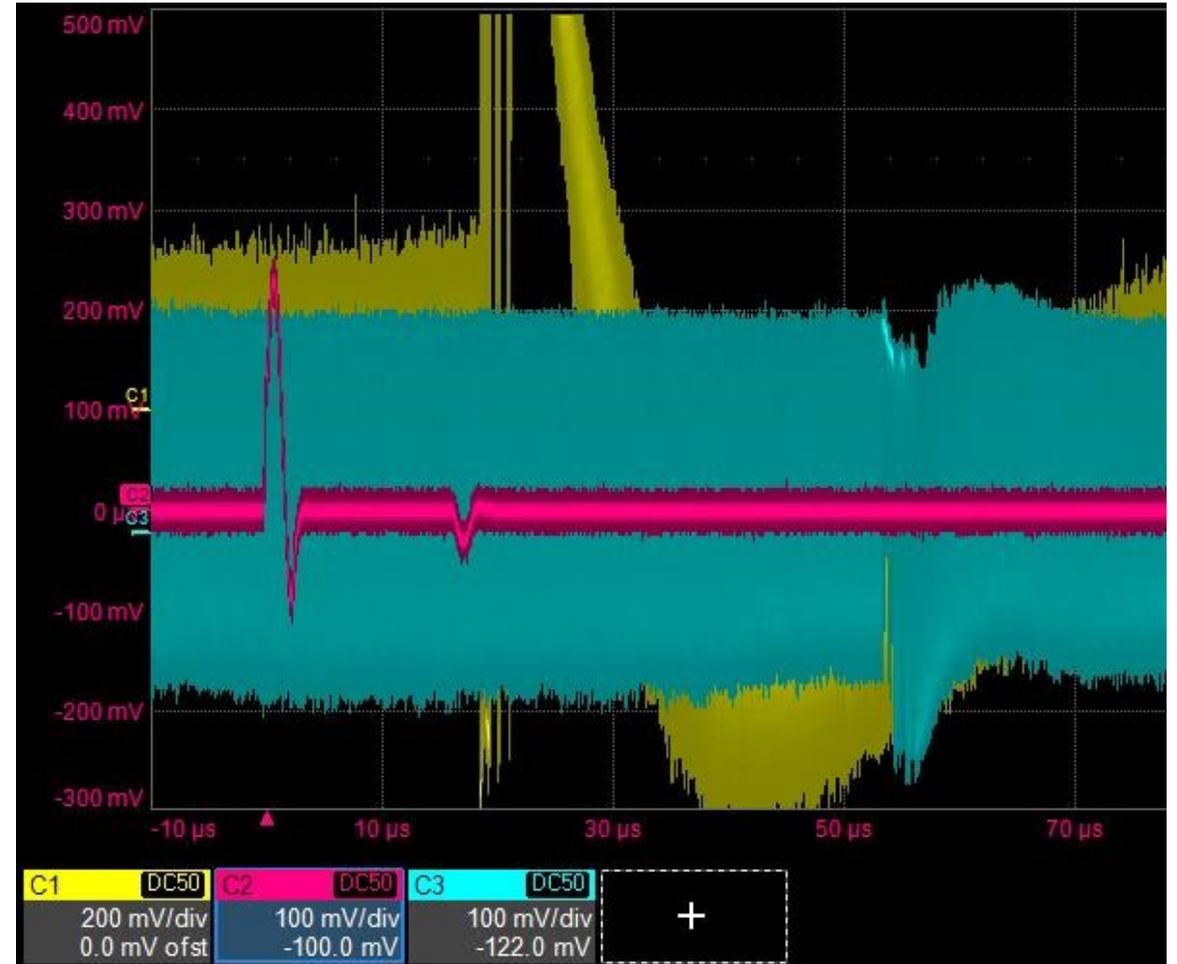

Issues and Improvements – BLR

- Dispersion compensation fibre in DCM causes a time delay relative to PDV channels
 - Approximately 40 μ s in this system
- Add a fiducial pulse during experiment for PDV and BLR channel cross-timing
- Measure probe standoff using OBR every time so movement can be measured relative to probe position if required
- Package system in 19" rack chassis for mobility

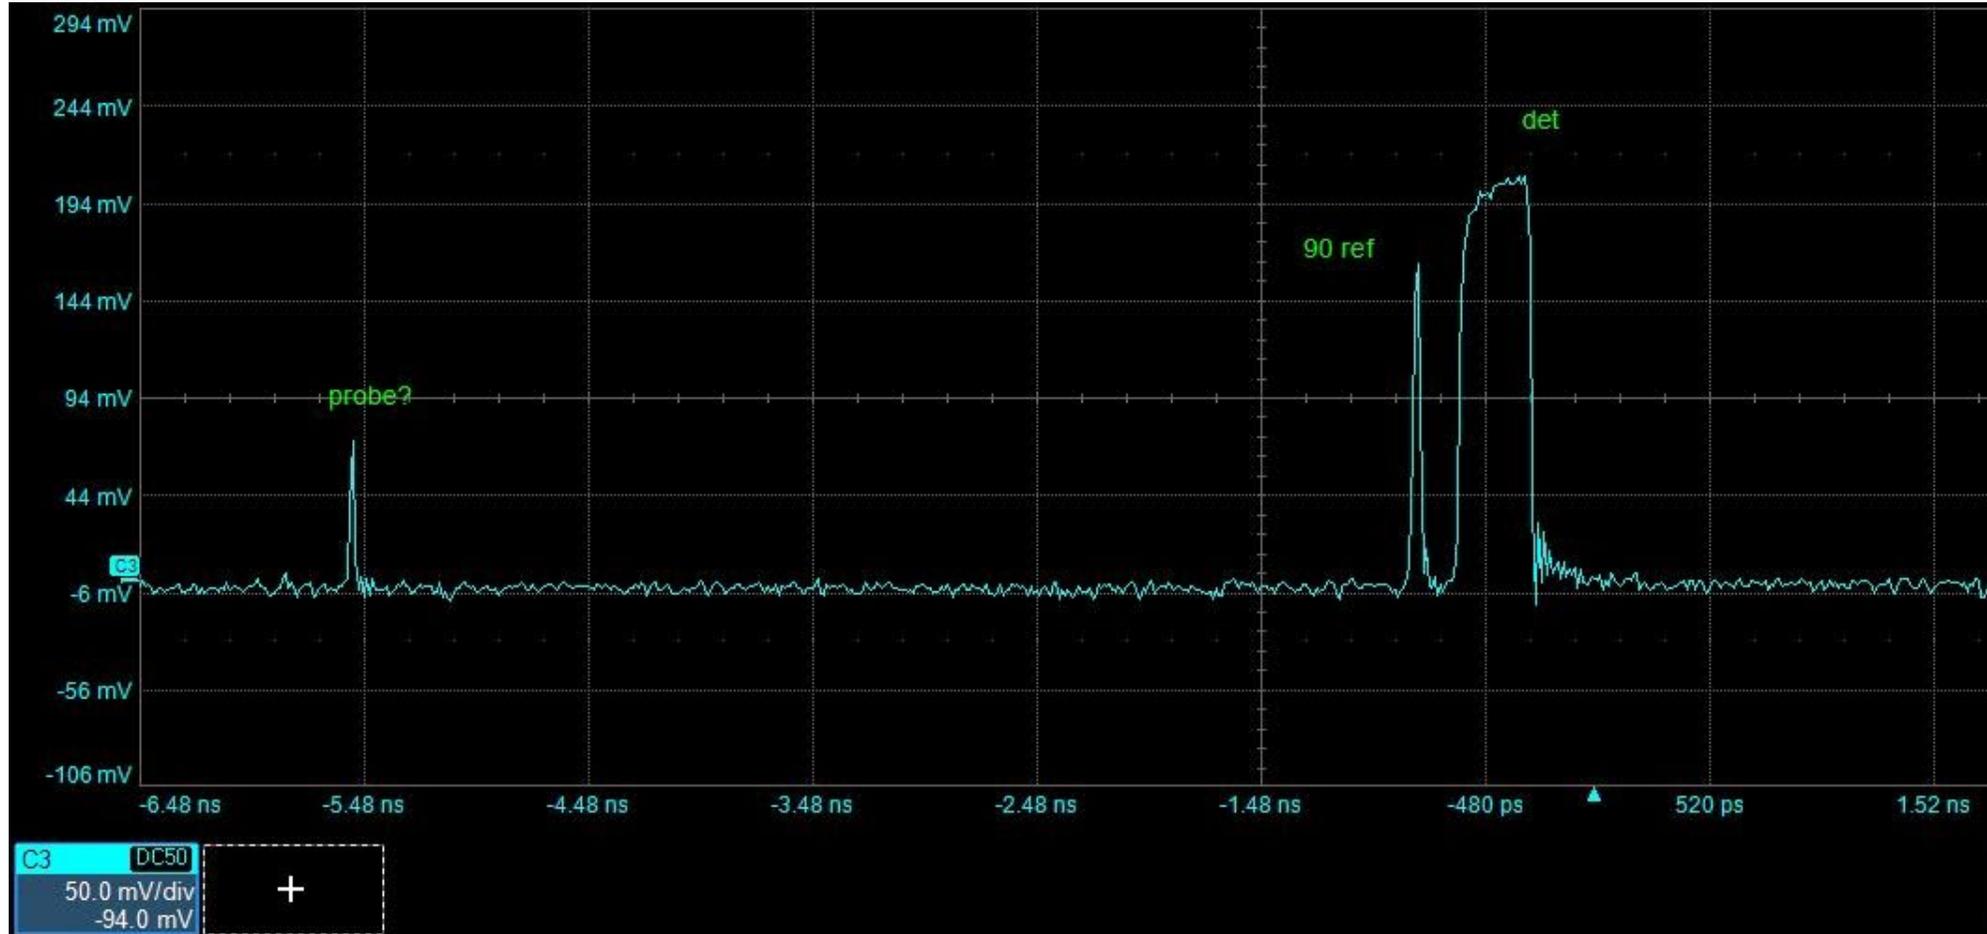

- Dechirp in analysis
- Find in-situ calibration frequency automatically

Issues and Improvements – PDV

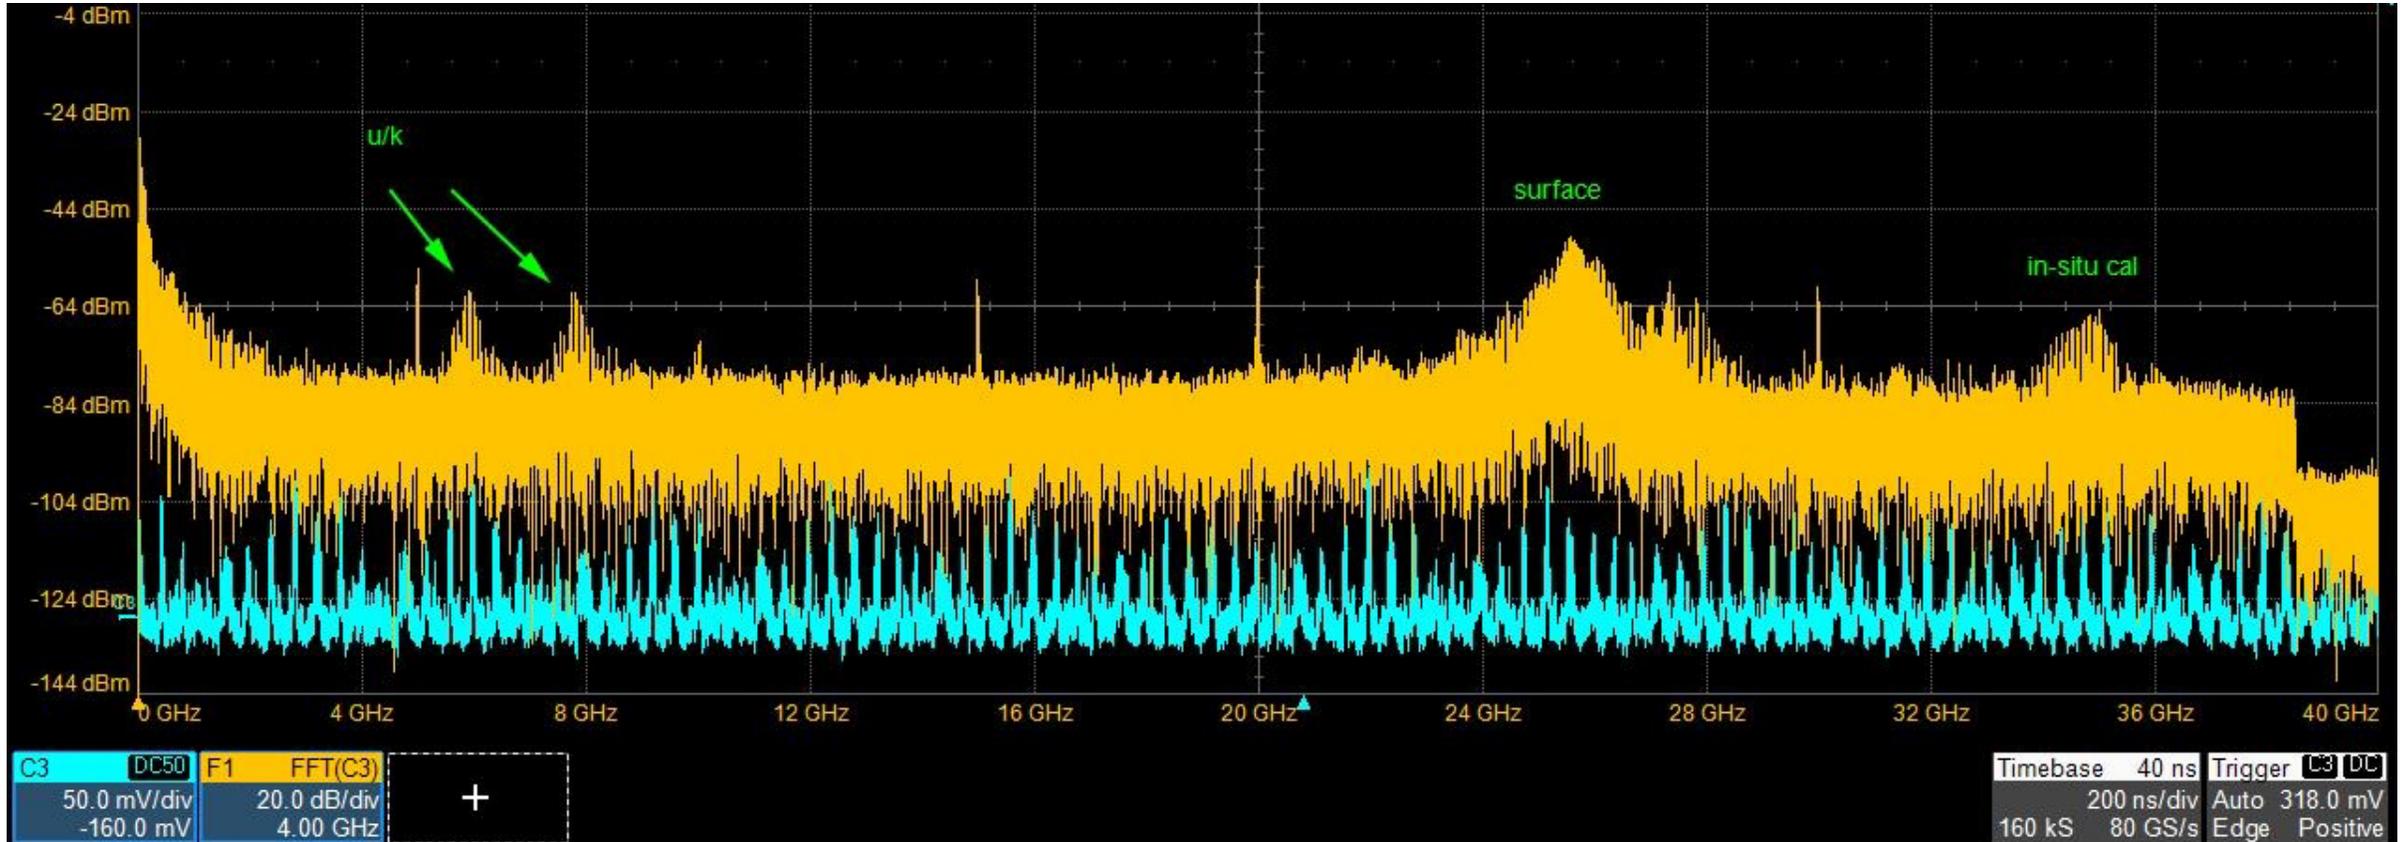

- 20 GHz receiver behaviour upon sharp drop in return signal
 - Bias takes tens of microseconds to recover
 - Causes clipping
- PDV should be upshifted more to separate main signal from 0-referenced signal

Appendix – where does this pulse come from?

Appendix – extra frequency peaks
